Abstract

Here goes the Abstract in English of your thesis followed by a list of keywords. The Abstract is a concise summary of the content of the thesis (single page of text) and a guide to the most important contributions included in your thesis. The Abstract is the very last thing you write. It should be a self-contained text and should be clear to someone who hasn't (yet) read the whole manuscript. The Abstract should contain the answers to the main scientific questions that have been addressed in your thesis. It needs to summarize the adopted motivations and the adopted methodological approach as well as the findings of your work and their relevance and impact. The Abstract is the part appearing in the record of your thesis inside POLITesi, the Digital Archive of PhD and Master Theses (Laurea Magistrale) of Politecnico di Milano. The Abstract will be followed by a list of four to six keywords. Keywords are a tool to help indexers and search engines to find relevant documents. To be relevant and effective, keywords must be chosen carefully. They should represent the content of your work and be specific to your field or sub-field. Keywords may be a single word or two to four words.

Keywords: here, the keywords, of your thesis

Abstract in lingua italiana

1 | Introcution to nuclear structure and phenomenology

In this chapter, a concise introduction to nuclear physics is provided, as a way to understand important physical properties of the system under study. First, in section **??**, we will discuss the main empirical facts about nuclides, such as particle density distribuion and binding energies. Then, we will address in section 1.1 simple phenomenological models historically employed to describe them, to move on to more advanced topics, that are able to complete the description of nuclear structure, which are nuclear pairing in section 1.2 and nuclear deformations in section 1.3. Finally, in section 1.4, we will see an overview of the nuclear fission process, for which exotic deformations are necessary for a complete description of the phenomena.

1.1. Nuclear structure models

1.1.1. Phenomenology of the NN interaction

The study of low energy hadron physics, has always been a challenging task. This is due to the known fact that the strong force, which is responsible for the attraction between the nucleons in a nuclei, is not perturbative at low energies, as opposed to the atomic case for the Coulomb interaction. It is possible nevertheless, to obtain a good description of the nuclear structure, by using empirical data obtained experimentally.

Binding energies

Let us start by the omnipresent physical quantity that is the binding energy of a nucleus. We can define it as the mass defect of the nucleus with respect to the constituents - protons and neutrons - isolated from eachother. If Z is the number of protons, N the number of neutrons, and $A = N + Z$ the nuclear mass, then the binding energy E_B is given by

$$E_B = (Zm_p + Nm_n - M)c^2 \tag{1.1}$$

where m_p is the proton mass, m_n the neutron mass, and M the nucleus mass.

In figure 1.1, the binding energy per nucleon E_B/A of nuclei as a function of A is plotted. As shown in the figure, the binding energy per nucleon rapidly saturates and stalls around 7 MeV just after $A = 4$, this striking behaviour is due to nucleons interacting only with near neighbours, since the strong force is a short-range interaction, otherwise, the trend would follow a behaviour of $A(A-1)$ as in the Coulomb case.
Figure 1.1: Binding energy of nuclei as a function of A.

Nuclear density

An important aspect of nuclear phenomenology which can be easily obtained through electron scattering experiments [24] is the nuclear density. It can be very well represented by a Fermi-like distribution, which reads

$$\rho(r) = \frac{\rho_0}{1 + e^{\frac{r - R_0}{a}}}, \tag{1.2}$$

where R_0 is the nuclear radius, which can be parametrized as $R_0 = r_0 A^{1/3} \approx 1.2 A^{1/3}$, and a is the diffusivity, whose value determines how sharp the density drops from its saturation value $\approx \rho_0$ to ≈ 0. The saturation density ρ_0 is generally universal for all nuclei amounting to ≈ 0.16 fm^{-3}.

1.1.2. Nuclear models

The description of nuclear structure has been proven to be a difficult task over the years. Due to the extremely rich phenomenology of nuclei and the challenges brought by the strong force, as we shall see, many models and further approximations to give a satisfac-

tory description of all nuclides have been proposed.

1.1.3. Liquid drop model

One, if not the first successful model, is the liquid drop model. It is based on the assumption that the nucleus behaves as a liquid droplet, where forces among consituents tend to saturate. This hypothesis, formulated by G. Gamow culminated in the formalization of the semi-empirical mass formula (SEMF) by N. Bohr and C. F. von Weizsäcker in 1935 [53], which reads

$$E_B = a_V A - a_S A^{2/3} - a_C \frac{Z(Z-1)}{A^{1/3}} - a_A \frac{(N-Z)^2}{A} + \delta_P \qquad (1.3)$$

where E_B is the binding energy of the nucleus. Each term has a different physical and phenomenological meaning:

- $a_V A$ is the volume energy of the nucleus, given by the approximately constant binding energy per nucleon, which makes the total energy roughly proportional to A;

- $a_S A^{2/3}$ is the surface energy, a correction to the volume energy due to outer nuclei – on the surface – interacting with fewer nucleons than those in the inner bulk;

- $a_C Z(Z-1)/A^{1/3}$ is the approximation to the Coulomb energy repulsion of the nucleus, assuming the protons are distributed uniformly;

- $a_A (N-Z)^2/A$ is the asymmetry energy, which is due to the Pauli exclusion principle, since protons and neutrons occupy their respective states, a high imbalance of one species or the other implies loosely bound nucleons, thus a higher energy contribution of those states; and

- δ_P refers to the pairing energy of the nucleus, whose physical significance will be later discussed in section 1.2.

The SEMF can be fitted on current data to get a good estimate of binding energies [3], but it still lacks the ability of describing many aspects of nuclear structure, mainly, the nuclear shell structure, which can account for magic numbers, nuclear deformations, and so on.
Figure 1.2: Visual representation of the liquid drop model from [20]

1.1.4.   Shell structure

The shell model, accounts for the effect of a mean field, central potential, to which nucleons are subjected. Unlike the 'atomic' case, we don't have an exact source of this field, since it's generated by the nucleons themselves. Nonetheless, the formulation of a potential which reproduces experimental data has been proven to be successful.

The so called Woods-Saxon potential is the empirical field used in this kind of model. It can take different parametrizations depending on the data that one wants to reproduce. It reads

$$U(\boldsymbol{r}) = -\frac{U_0(A, N)}{1 + e^{\frac{r-R}{a}}} \tag{1.4}$$

where U_0 is the potential depth

$$U_0(A, N) = U_0\left(1 \pm \kappa \frac{2N - A}{A}\right) \tag{1.5}$$

where the $+$ and $-$ signs refer to protons and neutrons respectively. R refers to the radius of the nuclear surface, generally parametrized as

$$R = r_0 A^{1/3} \tag{1.6}$$

and a is the surface diffuseness, as in the density expression in (1.2), which motivates the reason for such a construction in equation (1.4), it has the shape of the nuclear density.

Spin-orbit coupling   The success of the shell model is due to the possibility of accounting for spin-orbit interactions, included through a term which reads

$$U_{\mathrm{LS}}(\boldsymbol{r}) = U_0^{\mathrm{LS}}\left(\frac{r_0}{\hbar}\right)^2 \frac{1}{r}\frac{\mathrm{d}}{\mathrm{d}r}\left(\frac{1}{1 + e^{\frac{r-R}{a}}}\right). \tag{1.7}$$

Coulomb interaction   In the spherical case, the coulomb interaction can be taken as the energy potential produced by a sphere of charge Z and radius R, which reads

$$U_{\mathrm{C}}(r) = Ze^2 \begin{cases} \frac{3-(r/R)^2}{2R} & r \leq R \\ \frac{1}{r} & r > R \end{cases} \tag{1.8}$$

The complete Hamiltonian then reads

$$\hat{H} = \hat{T} + U + U_{\mathrm{LS}} + U_C \tag{1.9}$$

where U_C is present only when solving for the proton shells. The solution to the eigenvalue problem $\hat{H}\psi = E\psi$ is of the form

$$\psi_{nljm_j} = \frac{u_{nl}(r)}{r}[Y_l(\hat{\boldsymbol{r}}) \otimes \chi_{1/2}]_{jm_j} \tag{1.10}$$

where $Y_{nl}(\hat{\boldsymbol{r}})$ is the spherical harmonic function of degree l and order m, the $\hat{r}$ is used to denote dependence on the azimuthal and polar angles of $\boldsymbol{r}$ and $\otimes$ takes the meaning of the angular momentum coupling and $u_{nl}(r)$ satisfies the reduced Schrödinger equation

$$\left(-\frac{\hbar^2}{2m}\frac{\mathrm{d}^2}{\mathrm{d}r^2} + \frac{\hbar l(l+1)}{2mr^2} + U(r)\right)\psi_{nl} = E\psi_{nl} \tag{1.11}$$

Harmonic oscillator

A small digression on the harmonic oscillator is in order. The solution of the spherical potential

$$U_{\mathrm{HO}}(\boldsymbol{r}) = \frac{1}{2}m\omega^2 r^2, \tag{1.12}$$

produces the spherical harmonic oscillator basis, which for the lowest bound state of a Woods-Saxon potential, where ω is taken as $41/A^{1/3}$ MeV, shares very similar states. As a matter of fact, the harmonic oscillator is very often used to perform basis calculations in nuclear physics. We will see in section 3.3 that a harmonic oscillator basis is used as starting guess for the numerical solution of a Woods-Saxon potential.

Shell structure

A graphical representation of the shells is shown in figure 1.3 for a Woods-Saxon potential.
Figure 1.3: Graphical representation of the shell model solution.

1.2. Nuclear pairing

In the semi-empirical mass formula (1.3), the δ_p term is parametrised as

$$\delta_p = \begin{cases} +\delta_0 & \text{if N and Z are even,} \\ 0 & \text{if A is odd,} \\ -\delta_0 & \text{if N and Z are odd,} \end{cases} \qquad (1.13)$$

hence having an even number of neutrons and/or protons increases the binding energy of the nucleus. A common choice for δ_0 is

$$\delta_0 = 12 A^{1/2} \text{ MeV.}$$

This is a phenomena closely related to superconductivity, as nucleons of the same type form pairs that lie in higher energy states. An experimental evidence of this fact is knwon as odd-even staggering, where the separation energy

$$S_n = E_B(A, Z) - E_B(A - 1, Z), \qquad (1.14)$$

is higher for even A, an increase that corresponds to the energy necessary to break a pair. We will see in section 2.2 the two main methods to account for pairing at a microsopic level.

1.3. Nuclear deformations

We shall now give a description of the nuclear shape in a formal structure. We will start by describing the simplest case, the one of a quadrupole deformation. After that, we will discuss the more general case of trixial, octupole, and parity breaking deformations.

1.3.1. Quadrupole deformation

Assuming the nuclear volume to be evaluated as

$$V(A) = \frac{4}{3}\pi R^3 \tag{1.15}$$

Let us suppose to consider variations of the nuclear radius R in terms of spherical harmonics

$$R(\theta, \phi) = R_0 \left[1 + \sum_{\lambda\mu} \alpha_{\lambda\mu} Y_{\lambda\mu}(\theta) \right] \tag{1.16}$$

where the moments $\alpha_{\lambda\mu}$ defined as

$$\alpha_{\lambda\mu} = \int Y_{\lambda\mu}^*(\theta, \phi) R(\theta, \phi) d\Omega \tag{1.17}$$

are considered small, in the sense that $|\alpha_{\lambda\mu}|^2 \ll |\alpha_{\lambda\mu}|$. We have that Y_{00} is constant, so its moment does not produce an interesting variation. We can set $\alpha_{00} = 0$. Since Y_{10}, Y_{11} and Y_{1-1} are odd for $\theta + \pi$ and $\phi + \pi$, we have that $\alpha_{1\mu}$ vanishes in a reference frame in which the centre of mass is at the origin.

Now, let us consider only $\alpha_{2\mu}$ coefficients and neglect higher degree terms, so that the deformation is purely quadrupolar, then the radius reads

$$R(\theta, \phi) = R_0 \left[1 + \sum_{\mu=-2}^{2} \alpha_{2\mu} Y_{2\mu}(\theta, \phi) \right]. \tag{1.18}$$

If we move to the reference frame in which the inertia tensor, proportional to the coefficients $\alpha_{2\mu}$, is diagonal, which is known as intrinsic frame, then the sum $\alpha_{21} Y_{21}^* + \alpha_{2-1} Y_{2-1}^*$

vanishes. Since R is a real valued function, we have the relation

$$\alpha_{\lambda\mu}Y_{\lambda\mu} + \alpha_{\lambda-\mu}Y_{\lambda-\mu} = 2\,\mathrm{Re}\{\alpha_{\lambda\mu}Y_{\lambda\mu}\}, \tag{1.19}$$

as a consequence, the resulting expansion reads

$$
\begin{aligned}
R(\theta,\phi) &= R_0\left[1 + a_{20}Y_{20} + 2\,\mathrm{Re}\{a_{22}Y_{22}\}\right] \\
&= R_0\left[1 + \sqrt{\frac{5}{16\pi}}\left(a_{20}(3\cos^2\theta - 1) + 2a_{22}\sqrt{3}\sin^2\theta(\cos^2\phi - \sin^2\phi)\right)\right].
\end{aligned} \tag{1.20}
$$

If we perform the substitution

$$a_{20} = \beta\cos(\gamma) \tag{1.21}$$

$$a_{22} = \beta\sin(\gamma) \tag{1.22}$$

and express the variation of R along the cartesian axes, we get

$$R_x - R_0 = \delta R_x = \sqrt{\frac{5}{4\pi}}\beta R_0 \cos\left(\gamma - \frac{2\pi}{3}\right), \tag{1.23}$$

$$R_y - R_0 = \delta R_y = \sqrt{\frac{5}{4\pi}}\beta R_0 \cos\left(\gamma + \frac{2\pi}{3}\right), \tag{1.24}$$

$$R_z - R_0 = \delta R_z = \sqrt{\frac{5}{4\pi}}\beta R_0 \cos\gamma. \tag{1.25}$$

Assuming the value of β to always be positive, in the case $\gamma = 0$, $\delta R_x = \delta R_y < \delta R_z$, meaning the nucleus is in a *prolate* configuration; while in the case of $\gamma = \pi/3$, $\delta R_x = \delta R_y > \delta R_z$, meaning the nucleus has an *oblate* shape. A general convention is to write β with a negative sign in the oblate case, and a positive sign in the prolate case.

By using trigonometric identities, it is trivial to show that unique shapes are found only for $\gamma \in [0; \pi/3]$, if γ takes a value different from 0 or $\pi/3$, the shape is said to be triaxial, meaning $\delta R_z \neq \delta R_x \neq \delta R_y$, the nucleus has no more rotational symmetries and is only symmetric for reflections along the (x, y), (x, z) and (y, z) planes, which also induces parity symmetry.

1.3.2. Nilsson model

To understand the effect on single-particle motion of a deformed potential, we can consider the case of an axially deformed harmonic oscillator potential, for which $\omega_z \neq \omega_x = \omega_y = \omega_\perp$, meaning the oscillator frequency takes on a different value on the z axis than in the x and y axes.

To treat the deformation perturbatively, we can assume that the various frequencies deviate from the common $\omega_0 = 41/A^{1/3}$ MeV, in which case they read

$$\omega_z = \omega_0 - \frac{2}{3}\varepsilon, \tag{1.26}$$

$$\omega_\perp = \omega_0 + \frac{1}{3}\varepsilon, \tag{1.27}$$

this definition of the frequencies satisfies the conservation of volume, at lowest order in ε, assumed to hold for

$$\omega_0^3 = \omega_z \omega_\perp^2. \tag{1.28}$$

We can thus write the single-particle Hamiltonian in the deformed potential as

$$H = H_0 + \varepsilon H_1, \tag{1.29}$$

$$H_0 = -\frac{\hbar^2}{2m}\nabla^2 + \frac{1}{2}m\omega_0^2 r^2, \tag{1.30}$$

$$\varepsilon H_1 = \frac{1}{3}\omega_0^2\varepsilon(x^2 + y^2 - 2z^2) = -\frac{1}{3}\sqrt{\frac{16\pi}{5}}m\omega_0^2\varepsilon r^2 Y_{20}. \tag{1.31}$$

H_0 is the usual spherical harmonic potential, for which the eigenfunctions, expressed through the usual quantum numbers $|nljm_j\rangle$ are known. Assuming ε to be small, we can evaluate the first order correction of H_1 to the system, which reads

$$\Delta E = \langle nljm_j | \varepsilon H_1 | nljm_j \rangle, \tag{1.32}$$

$$= -\frac{1}{3}\sqrt{\frac{16\pi}{5}}\varepsilon m\omega_0^2 \int r^2 u_{nl}(r) \langle jm_j | Y_{20} | jm_j \rangle \, dr, \tag{1.33}$$

$$= \frac{\varepsilon}{6}m\omega_0^2 \int r^2 u_{nl}(r)\frac{3m_j^2 - j(j+1)}{j(j+1)} dr, \tag{1.34}$$

thus in the limit of large j, states with the maximum total angular momentum projection m_j are shifted upwards, while states with the minimum m_j are shifted downwards; moreover, eigenstates with $\pm m_j$ are degenerate, as expected by the reflection symmetry of the Hamiltonian if the z axis is inverted. Adding further empirical terms to reproduce experimental data, and the spin-orbit coupling, results in the formulation of the Nilsson model [38]. In figure 1.4, a graphical representation of the energy levels in the Nilsson model is shown [54].
Figure 1.4: Nilsson model energy levels trends, as a function of ε.

Deformed Woods-Saxon

Recent studies of deformed nuclei have been carried out using empirical potentials such as deformed Woods-Saxon potentials [17, 26]. In these models, the nuclear shape is expanded as

$$R(\theta) = R_0 \left[1 + \sum_{\lambda}^{L} \beta_\lambda Y_{\lambda 0} \right], \tag{1.35}$$

so that the solution is axially symmetric, and the problem is reduced to just the (r, θ) coordinates, in which we can write the potential as

$$U_{\text{WS}}(r, \theta) = -\frac{U_0(A, N)}{1 + e^{\frac{r - R(\theta)}{a}}}. \tag{1.36}$$

1.3.3.   Octupole deformations and parity breaking

While quadrupole deformations concern nuclei across the whole chart, octupole deformations are much less common, being found only in heavier nuclei. Under the parity

operation $\mathcal{P} : \boldsymbol{r} \mapsto -\boldsymbol{r}$, coefficients of the spherical harmonics transform as

$$\mathcal{P}\alpha_{\lambda\mu} = (-1)^{\lambda}\alpha_{\lambda\mu}, \tag{1.37}$$

hence a nuclear octpuole deformation, whose degree $\lambda = 3$, would break parity symmetry. In figure 1.5 a graphical representation of the spherical harmonics for $\lambda = 3$ and $\mu = 0, 2$ is shown.

Figure 1.5: Graphical representation of possible octupole deformations. On the left, the axially symmetric Y_{30} deformation, on the right, the non-axial octupole deformation Y_{32}.

1.4.   Nuclear fission

Nuclear fission is the process by which a nucleus splits into two – sometimes three – nuclei, whether spontaneously, or induced by a reaction with a neutron. The physics that governs nuclear fission is the one of many-body, large amplitude collective modes, which elongate the the nuclear shape, until the so called *fission barrier* is surmounted and the path to the energy minimum is one where the nuclei fragments itself.

Spontaneous fission model

It should be ovious that a formal treatment of deformations and collective modes is necessary to give a theoretical description of fission reactions. We can derive a simple spontaneous fission model by studying the effect of a simple axial quadrupole deformation on the semiempirical mass formula 1.3.

Let us assume that the nuclear radius may be expanded, as previously done in section 1.3, as

$$R = R_0[1 + \alpha_{20}Y_{20}]. \tag{1.38}$$

Assuming the nuclear volume is conserved across the fission path, the volume energy will not change. As for the surface energy, its variation can be expressed at the lowest order in α_{20} as

$$\Delta E_{\text{surf}} = E_{\text{surf}} - E_{0,\text{surf}} = E_{0,\text{surf}}\frac{2}{5}\alpha_{20}^2. \tag{1.39}$$

Regarding the Coulomb energy, the variation is given by

$$\Delta E_{\text{coul}} = E_{\text{coul}} - E_{0,\text{coul}} = -E_{0,\text{coul}} \tag{1.40}$$

Since the neutron and proton count does not change, the surface and Coulomb energies are the only contributions to the total energy difference. We can write

$$\Delta E = \frac{2}{5}\alpha_{20}^2 a_s A^{2/3} - \frac{1}{5}\alpha_{20}^2 a_c Z^2 A^{-1/3}, \tag{1.41}$$

if we set equation (1.41) to zero, we get, other than the undeformed solution for $\alpha_{20} = 0$,

$$\frac{Z^2}{A} = \frac{2a_s}{a_c}, \tag{1.42}$$

where the ratio $2a_s/a_c$ amounts to ≈ 50 in typical parametrizations of the SEMF. In figure **??**, the energy change ΔE is plotted as a function of α_{20}^2 different Z^2/A, which is called *fissility parameter*; as shown in the figure, when the fissility parameter is larger than 50, the energy change becomes negative, favouring a configuration in which the nucleus fragments due to the spontaneous fission.

1.4.1. Octupole deformations

2 | Energy functional

2.1. Hartree-Fock theory

While a phenomenological description of bulk nuclear structure properties can be carried out using the liquid drop model or empirical mean-field potentials like Woods-Saxon or Nilsson, as we have seen in section 1.1, this is not sufficient to accurately reproduce all experimental ground state observables, systematically throughout the chart of nuclei, in an accurate manner.

A more rigorous approach needs to take into account the fact that the mean field which the nucleons interact with, is generated by the nucleons themselves. Starting from the many-body hamiltonian of the system, we will be able to extract a single particle Hamiltonian, including an effective mean field potential generated by the effective microscopic force, through the use of the Hartree-Fock method.

We start by writing the many-body hamiltonian of the system, which is a collection of A interacting fermions, given by

$$\hat{H} = \hat{T} + \hat{V} = \sum_i -\frac{\hbar^2}{2m}\nabla_i^2 + \sum_{i<j} v_{ij}^{(2)} + \sum_{i<j<k} v_{ijk}^{(3)} + \dots \tag{2.1}$$

The corresponding Schrödinger equation reads

$$\hat{H}\Psi = E\Psi. \tag{2.2}$$

2.1.1. Variational principle

Since $\hat{H}$ is a many body operator, finding its eigenstates would be a rather challenging task. To our aid, comes the variational principle, from which we can show that equation (2.2) is equivalent to

$$\delta E[\Psi] = \delta \frac{\langle \Psi| E |\Psi\rangle}{\langle \Psi|\Psi\rangle} = 0. \tag{2.3}$$

The variation (2.3) can be obtained from an arbitrary variation of Ψ, which can be done indipendently on $\langle\Psi|$ and $|\Psi\rangle$, since Ψ is complex, yielding

$$\langle\delta\Psi|\,\hat{H}-E\,|\Psi\rangle+\langle\Psi|\,\hat{H}-E\,|\delta\Psi\rangle=0 \tag{2.4}$$

since the variation is arbitrary, we can multiply by a phase factor $|\delta\Psi\rangle\mapsto i\,|\delta\Psi\rangle$ and get

$$-i\,\langle\delta\Psi|\,\hat{H}-E\,|\Psi\rangle+i\,\langle\Psi|\,\hat{H}-E\,|\delta\Psi\rangle=0. \tag{2.5}$$

Combining equations (2.4) and (2.5), we get

$$\langle\delta\Psi|\,\hat{H}-E\,|\Psi\rangle=0. \tag{2.6}$$

Again, since the variation is arbitrary, equation (2.6) satisfies equation (2.2).

Ground state

Since we always restrict ourselves to a certain subspace of the full Hilbert space, we can only find an approximate solution to the eigenvalue problem. Expanding this solution on the complete set of exact eigenstates of $\hat{H}$, we have

$$|\Psi\rangle=\sum_n a_n\,|\Psi_n\rangle \tag{2.7}$$

the total energy amounts to

$$E[\Psi]=\frac{\sum_{nn'}\langle a_{n'}\Psi_{n'}|\,\hat{H}\,|a_n\Psi_n\rangle}{\sum_{nn'}\langle a_{n'}\Psi_{n'}|a_n\Psi_n\rangle}=\frac{\sum_n E_n|a_n|^2}{\sum_n|a_n|^2}\geq\frac{\sum_n E_0|a_n|^2}{\sum_n|a_n|^2}\geq E_0, \tag{2.8}$$

where E_0 is the ground state energy of the system. The orthonormality of the Hamiltonian eigenfunctions $\langle\Psi_{n'}|\Psi_n\rangle=\delta_{nn'}$ has been used. Equation (2.8) tells us that the minimum of the functional $E[\Psi]$ in any variationl subspace we are considering is bound from below by the true ground state energy.

2.1.2. Hartree-Fock equations

The Hartree-Fock method is the application of the variational principle (2.6) to a system of independent particles, whose wavefunction takes the form of a Slater determinant,

which reads

$$\Psi = \frac{1}{\sqrt{A!}} \sum_{\{p\}} (-1)^p \varphi_{p(1)}(\boldsymbol{r}_1) \dots \varphi_{p(A)}(\boldsymbol{r}_A) \tag{2.9}$$

where φ_i are the single-particle orthonormal states, which serve the role of variational parameters in Hartree-Fock. The Slater determinant sums over all possible permutations of the A fermions on the single particle states, with a $-$ sign according to the parity of the permutation. The Slater determinant statisfies the permutation symmetry of fermions, so that the Pauli exclusion principle is not violated.

To ensure the orthonormality of the single-particle states, we need to add a Lagrange multiplier to the variation (2.6) of E, which ends up reading

$$\delta \left(E[\Psi] - \sum_i \lambda_i \int \varphi_i^* \varphi_i d\boldsymbol{r} \right) = 0. \tag{2.10}$$

We can write explicitly $E[\Psi] = \langle \Psi | \hat{T} + \hat{V} | \Psi \rangle = \langle \Psi | \hat{T} | \Psi \rangle + \langle \Psi | \hat{V} | \Psi \rangle$ through $\{\varphi_i\}$

$$\langle \Psi | \hat{T} | \Psi \rangle = \sum_i^A -\frac{\hbar^2}{2m} \int \varphi_i^*(\boldsymbol{r}) \nabla^2 \varphi_i(\boldsymbol{r}) d\boldsymbol{r} = \sum_i \langle i | t | i \rangle \tag{2.11}$$

$$\langle \Psi | \hat{V} | \Psi \rangle = \frac{1}{2} \sum_{ij} \int \varphi_i^*(\boldsymbol{r}) \varphi_j^*(\boldsymbol{r}') v_{ij}(\boldsymbol{r}, \boldsymbol{r}') \varphi_i(\boldsymbol{r}) \varphi_j(\boldsymbol{r}') d\boldsymbol{r} d\boldsymbol{r}' \tag{2.12}$$

$$- \frac{1}{2} \sum_{ij} \int \varphi_i^*(\boldsymbol{r}) \varphi_j^*(\boldsymbol{r}') v_{ij}(\boldsymbol{r}, \boldsymbol{r}') \varphi_i(\boldsymbol{r}') \varphi_j(\boldsymbol{r}) d\boldsymbol{r} d\boldsymbol{r}' \tag{2.13}$$

$$= \frac{1}{2} \langle ij | \overline{v} | ij \rangle. \tag{2.14}$$

If we use $\varphi_i^*(\boldsymbol{r})$ as the quantity to be varied in equation (2.10), we get the *Hartree-Fock equations*

$$-\frac{\hbar^2}{2m} \nabla^2 \varphi_i \tag{2.15}$$

$$+ \frac{1}{2} \sum_j^A \int \varphi_j^*(\mathbf{r}') v_{ij}(\mathbf{r}, \mathbf{r}') \varphi_j(\mathbf{r}') \varphi_i(\mathbf{r}) d\mathbf{r}' \tag{2.16}$$

$$- \frac{1}{2} \sum_j^A \int \varphi_j^*(\mathbf{r}') v_{ij}(\mathbf{r}, \mathbf{r}') \varphi_j(\mathbf{r}) \varphi_i(\mathbf{r}') d\mathbf{r}' = h\varphi_i = \varepsilon_i \varphi_i \tag{2.17}$$

here the Lagrange multipliers λ_i have been replaced by ε_i, since they can be interpreted as the energy of the single-particle states.

Now, a couple of remarks are in order.

Exchange interaction   The first interaction term (2.16), called Hartree term, arises from considering independent particles, and is also routinely found in classical physics. The second one in (2.17), called Fock term, or exchange term, takes the form of an integral operator and is present when considering quantum mechanical indistinguishable particles. For what concerns the solution of equation (2.15), the Fock term is problematic, and can be avoided using zero-range forces like the Skyrme one [48], which is used in the present work, since it renders the exchange term as a local one.

Self-consistent solution   Even if the interaction terms are local, the equation is still highly non-linear, since the mean field potential will be a function of the eigenfunctions themselves. The consequece is that the solution needs to be found *self-consistently*, that is, by solving for the set of eigenfunctions $\{\varphi_i\}$, using them to build the new mean field, and solving again, repeating the process until convergence.

2.1.3.   Symmetries in Hartree-Fock

Since the objective of this work is to solve the Hartree-Fock equations without spatial symmetry assumptions, it is useful to first understand how symmetries propagate along the self-consistent calculation.

We start by defining the creation and annihilation operators of the single particle hamiltonian eigenstates, $a_i^\dagger, a_i$, which abide the usual anticommutation relations of fermions

$$\{a_i, a_j^\dagger\} = \delta_{ij} \tag{2.18}$$

If we expand on a different, orthonormal complete basis $\{\chi_l\}$, we can write the corresponding creation and annihilation operators $c_l^\dagger, c_l$ as

$$\varphi_k = \sum_l D_{lk}\chi_l \tag{2.19}$$

$$a_k^\dagger = \sum_l D_{lk}c_l^\dagger \tag{2.20}$$

$$a_k = \sum_l D_{lk}^\dagger c_l \tag{2.21}$$

Since orthonormality is guaranteed for both sets, taking $\langle \varphi_j | \varphi_k \rangle$ yields

$$\delta_{jk} = \langle \varphi_j | \varphi_k \rangle = \sum_{ll'} D_{l'j}^\dagger D_{lk} \langle \chi_l | \chi_l' \rangle \implies DD^\dagger = 1, \tag{2.22}$$

meaning that D is a unitary transformation. We can define the density matrix as

$$\rho_{ll'} = \langle\Psi|\,c_{l'}^\dagger c_l\,|\Psi\rangle\,,\tag{2.23}$$

whose trace is equal to the particle number A, as per equation (2.24)

$$\mathrm{Tr}\,\rho = \sum_{ll}\langle\Psi|\,c_l^\dagger c_l\,|\Psi\rangle = \sum_{ll}\langle\Psi|\,a_l^\dagger a_l\,|\Psi\rangle = \sum_{ll}^{A}\langle\Psi|\Psi\rangle = A.\tag{2.24}$$

Writing the many body hamiltonian (2.2) in the arbitrary basis of second quantization operators $c_l^\dagger, c_l$, we get

$$\hat{H} = \sum_{l_1 l_2} t_{l_1 l_2} c_{l_1}^\dagger c_{l_2} + \frac{1}{4}\sum_{l_1 l_2 l_3 l_4}\overline{v}_{l_1 l_2 l_3 l_4} c_{l_1}^\dagger c_{l_2}^\dagger c_{l_3} c_{l_4}\tag{2.25}$$

where $t_{l_1 l_2}$ and $\overline{v}_{l_1 l_2 l_3 l_4}$ are defined as

$$t_{l_1 l_2} = \langle-|\,c_{l_1} c_{l_2} t c_{l_1}^\dagger c_{l_2}^\dagger\,|-\rangle = \langle l_1 l_2|\,t\,|l_1 l_2\rangle\tag{2.26}$$

$$\overline{v}_{l_1 l_2 l_3 l_4} = \langle l_1 l_2 l_3 l_4|\,v\,|l_1 l_2 l_3 l_4\rangle - \langle l_1 l_2 l_4 l_3|\,v\,|l_1 l_2 l_4 l_3\rangle\,.\tag{2.27}$$

The minimization (2.10) can be restated as the variation of $\langle\Psi|\,\hat{H}\,|\Psi\rangle$, with respect to the density matrix $\rho_{ll'}$, which yields

$$h_{ll'} = \frac{\partial E[\rho]}{\partial\rho_{ll'}} = t + \sum_{kk'}\overline{v}_{lk'l'k}\rho_{kk'} = t + \Gamma_{ll'}\tag{2.28}$$

where $\Gamma_{ll'}$ is the mean field potential in the arbitrary basis. Being h diagonal in the Hartree-Fock basis, the self-consistent solution is the one for which

$$[h, \rho] = 0\tag{2.29}$$

holds.

Symmetry propagation

Let us suppose to start a Hartree-Fock calculation with an initial guess for which the corresponding density matrix $\rho^{(0)}$ is symmetric under the action of a many-body symmetry

operator S which commutes with the Hamiltonian

$$[S, \hat{H}] = 0. \tag{2.30}$$

It can be shown [43] that

$$S\Gamma[\rho]S^\dagger = \Gamma[S\rho S^\dagger]. \tag{2.31}$$

The single particle Hamiltonian h will then display the same property

$$Sh[\rho]S^\dagger = h[S\rho S^\dagger] = h[\rho] \tag{2.32}$$

meaning that h will be symmetric under the action of S, as well as the next iteration's density matrix $\rho^{(1)}$. The symmetry S gets propagated self-consistently until the minimum is found.

This has profound numerical implications, since the minimum energy configuration of a deformed nuclei can be reached only by starting guesses with the same broken symmetries. It can be the case that numerical noise allows to explore the full energy surface, but if one has to take into consideration the numerical cost of a bad guess, then it's still advantageous to start from a correct one in terms of symmetries.

2.1.4.   Broken symmetries

2.1.5.   Density Functional Theory

It shall be evident shortly, in section 2.3, that a more general approach to microscopic models has to be taken in order to give a satisfactory description of nuclei and nuclear matter. The method that we will briefly outline here is called Density Functional Theory (DFT).

DFT was introduced by P. Hohenberg and W. Kohn in 1964 [25], by proving two theorems. The **first** Hohenberg Kohn (HK) theorem states that the energy of a fermion system, subject to an external potential V_{ext} can be expressed solely as a functional of the particle density ρ of the system

$$E[\rho] = F[\rho] + \int V_{\text{ext}}\rho(\boldsymbol{r})d\mathbf{r}, \tag{2.33}$$

where $F[\rho]$ is a universal functional given by the type of fermions considered, while V_{ext} term is the external potential to which the system is subject to; when treating atomic nuclei, the potential is generated by the nucleons themselves, so this term will be omitted in the following. The **second** HK theorem states that the ground state of the system is

found by minimizing the functional (2.33) with respect to ρ.

HK theorems are fundamental but not constructive [14], since they do not provide a form for the functional F, which is intrinsic to the physics of the fermions at hand. A pragmatic approach to using DFT was outlined by Kohn and Sham in 1965 [29]. They proposed expressing the system as a set of non-interacting particles occupying auxiliary orbitals φ_i, which yield the particle density

$$\rho(\boldsymbol{r}) = \sum_i |\varphi_i(\boldsymbol{r})|^2 \tag{2.34}$$

and an energy functional of the form

$$E[\rho] = T[\rho] + E_H[\rho] + E_{\mathrm{xc}}[\rho]. \tag{2.35}$$

where T is the kinetic energy, which reads

$$T[\rho] = -\frac{\hbar^2}{2m} \sum_i \varphi_i^*(\boldsymbol{r}) \nabla^2 \varphi_i(\boldsymbol{r}) \tag{2.36}$$

and E_H is the classical Hartree term, which in an electronic system may read

$$E_H[\rho] = \iint \frac{\rho(\boldsymbol{r})\rho(\boldsymbol{r}')}{|\boldsymbol{r} - \boldsymbol{r}'|} d\boldsymbol{r} d\boldsymbol{r}' \tag{2.37}$$

while E_{xc} is an unknown exchange term. In electronic systems, the Hartree term is known (2.16) and the exchange term can be approximated thanks to the compensation of its error with the one of particles correlation neglection [37]. In nuclear physics, things are more complicated, since both terms are unknown; historically, effective interactions in HF have been used to extract an effective Hamiltonian density from which an energy density functional (EDF) can be formulated, whenever a pure interaction is not sufficient to describe nuclear systems, as we shall see in section 2.3.

2.2. Pairing in Hartree-Fock theory

In this section, we will discuss the two common approaches to include nuclear pairing in the HF theory. The aim of these few pages is to provide a brief overview of how the BCS equations are derived and understand the basics of the more general Hartree-Fock-Bogoliubov theory. The former method is the most widely implemented thanks to its low complexity [8, 13, 30], while the latter, more sophisticated and advanced, is the standard in modern codes [12, 36, 46], we will touch on it so that the reader may appriciate in

the numerical chapter the natural extension of this work to the more general Bogoliubov ansatz.

2.2.1. BCS theory

The BCS approximation, from Bardeen-Cooper-Schrieffer, is the same theory used to describe Cooper pairs in superconductivity, applied to the nuclear case. The ansatz of BCS is that nucleons are paired in states whose total angular momentum is zero, such a wavefunction can be expressed as $|JM\rangle = |00\rangle$ and reads

$$|00\rangle = \sum_m \langle jm_j j - m_j |00\rangle |j - m\rangle \tag{2.38}$$

Introducing the time-reversal operator $\hat{\mathcal{T}} : t \mapsto -t$, it acts on $|00\rangle$ as

$$\hat{\mathcal{T}} |jm\rangle = \widetilde{|jm\rangle} = (-1)^{j+m} |j - m\rangle, \tag{2.39}$$

using this relation, equation (2.38) becomes

$$|00\rangle = -\frac{1}{\sqrt{2j+1}} |jm\rangle \widetilde{|jm\rangle}. \tag{2.40}$$

Hence BCS amounts to using in the HF method the more general Slater determinant

$$|\text{BCS}\rangle = \prod_{k>0} (u_k + v_k a_k^\dagger a_{\tilde{k}}^\dagger) |-\rangle \tag{2.41}$$

where u_k and v_k are real parameters whose meaning will shortly be clear, k is short-hand for $|jm\rangle$, and $\tilde{k} = -k$ denotes the time-reversal state of k; the product runs over positive k only. The BCS wavefunction is the creation in the vacuum of quasi-paticles made of time-reversal paired particles, instead of individual ones. The normalization condition on the BCS wavefunction reads

$$1 = \langle \text{BCS}|\text{BCS}\rangle = \prod_{k>0} \langle -| (u_k + v_k a_k a_{\tilde{k}})(u_k + v_k a_{\tilde{k}}^\dagger a_k^\dagger) |-\rangle = \prod_{k>0} (u_k^2 + v_k^2) = 1 \tag{2.42}$$

which implies, for every pair k, the condition

$$u_k^2 + v_k^2 = 1. \tag{2.43}$$

Taking the expectation value of the particle number operator $\hat{N} = \sum_k a_k^\dagger a_k$ yields [5]

$$\langle \text{BCS}| \, \hat{N} \, |\text{BCS}\rangle = 2 \sum_{k>0} v_k^2, \tag{2.44}$$

while the expectation value of the particle number dispersion reads

$$\left\langle \Delta \hat{N}^2 \right\rangle = \left\langle \hat{N}^2 \right\rangle - \left\langle \hat{N} \right\rangle^2 = 4 \sum_{k>0} v_k u_k. \tag{2.45}$$

The consequence of this result is profound. The BCS ansatz does not assume a fixed number of particles, rather it becomes an observables of the system, with an expectation value that depends on how the parameters v_k^2 are set, which represent the probability of finding a particle in the k-th state. We can now write the many body Hamiltonian of the system as in equation (2.25)

$$\hat{H} = \sum_{k_1 k_2} t_{k_1 k_2} a_{k_1}^\dagger a_{k_2} + \frac{1}{4} \sum_{k_1 k_2 k_3 k_4} \overline{v}_{k_1 k_2 k_3 k_4} a_{k_1}^\dagger a_{k_2}^\dagger a_{k_3} a_{k_4} \tag{2.46}$$

and replace it with the Routhian

$$\langle \text{BCS}| \, \hat{H} - \lambda \hat{N} \, |\text{BCS}\rangle \tag{2.47}$$

so that the expected number of particles may be fixed, under the appropriate choice of λ, by the relation

$$\frac{\partial^2}{\partial N \partial \, \langle \text{BCS}| \, \hat{H} - \lambda \hat{N} \, |\text{BCS}\rangle} = \lambda. \tag{2.48}$$

the Lagrange multiplier λ takes on the meaning of the Fermi energy. We can now apply the variational principle (2.6) to (2.47) using the v_k as variational quantities, which yields

$$4\tilde{\varepsilon}_k^2 u_k^2 v_k^2 = \Delta_k^2 - \Delta_k^2 u_k^2 v_k^2, \tag{2.49}$$

where the pairing gap Δ_k is defined as

$$\Delta_k = -\sum_{k'} \overline{v}_{k\tilde{k}k'\tilde{k}'} v_{k'} u_{k'} \tag{2.50}$$

and the quantity $\tilde{\varepsilon}_k$ is defined as

$$\tilde{\varepsilon}_k = \frac{1}{2}\left[t_{kk} + t_{\tilde{k}\tilde{k}} - 2\lambda + \sum_{k'}(\overline{v}_{k\tilde{k}k'\tilde{k}'}v_{k'}u_{k'} + \overline{v}_{\tilde{k}k'\tilde{k}k'})v_{k'}^2 \right] \tag{2.51}$$

$$= \frac{1}{2}[h_{kk} + h_{\tilde{k}\tilde{k}}] - \lambda. \tag{2.52}$$

Introducing the quasi-particle energy

$$E_k = \sqrt{\tilde{\varepsilon}_k^2 + \Delta_k^2} \tag{2.53}$$

we can combine definitions (2.50) and (2.53) with equation (2.51), under the normalization condition (2.43), to get an equation for v_k^2

$$v_k^2 = \frac{1}{2} \pm \frac{|\tilde{\varepsilon}_k|}{2E_k}. \tag{2.54}$$

Since in the Hartree-Fock limit, where the occupations v_k^2 are equal to one below the fermi energy and zero above, and the gaps Δ_k vanish, rendering $E_k = \tilde{\varepsilon}_k$, we only select the solution

$$v_k^2 = \frac{1}{2} - \frac{\tilde{\varepsilon}_k}{2E_k}. \tag{2.55}$$

Using the normalization condition to write $u_k^2 = 1 - v_k^2$, and plugging it into the gaps definition (2.50), we arrive to the gap equation

$$\Delta_k = -\sum_{k'} \frac{\Delta_{k'}\overline{v}_{k\tilde{k}k'\tilde{k}'}}{2E_{k'}} \tag{2.56}$$

The system of equations (2.56, 2.43, 2.54, 2.53, 2.51), together with the condition $\left\langle \hat{N} \right\rangle = N$ is closed and can be solved numerically, usually through an effective pairing interaction.

2.2.2.   Hartree-Fock-Bogoliubov theory

The most general ansatz to account for pairing interactions in Hartree-Fock theory is the Hartree-Fock-Bogoliubov (HFB) theory, it allows a treatment of the mean-field and pairing interactions in a unified way, the quasi-particles created on the vacuum are the most general ones, instead of being time-reversal paired particles. Let us start by writing a Bogoliubov transformation from the particle basis c_i to a quasi-particle one

$$\beta_k^\dagger = \sum_l U_{lk}c_l^\dagger + V_{lk}c_l. \tag{2.57}$$

If we take the Hermitian conjugate of the relation (2.57), we get the transformation for β_k, we are then able to write in matrix form

$$\begin{pmatrix} \beta \\ \beta^\dagger \end{pmatrix} = \begin{pmatrix} U^\dagger & V^\dagger \\ V^T & U^T \end{pmatrix} \begin{pmatrix} c \\ c^\dagger \end{pmatrix} = \mathcal{W}^\dagger \begin{pmatrix} c \\ c^\dagger \end{pmatrix}, \tag{2.58}$$

where the matrix of matrices $\mathcal{W}$ reads

$$\mathcal{W} = \begin{pmatrix} U & V^* \\ V & U^* \end{pmatrix}. \tag{2.59}$$

Taking the product $\mathcal{W}^\dagger \mathcal{W}$ and imposing separate fermionic commutation relations of the operators $\beta, \beta^\dagger, c, c^\dagger$, we get that $\mathcal{W}$ is unitary, hence

$$\mathcal{W}^\dagger \mathcal{W} = \mathcal{W}\mathcal{W}^\dagger = I. \tag{2.60}$$

We can now invert equation (2.58) by multiplying both sides on the left by $\mathcal{W}$, which yields

$$\mathcal{W} \begin{pmatrix} \beta \\ \beta^\dagger \end{pmatrix} = \begin{pmatrix} c \\ c^\dagger \end{pmatrix}.$$

Using the Messiah-Bloch decomposition [16], we can write the unitary matrix $\mathcal{W}$ as

$$\mathcal{W} = \begin{pmatrix} D & 0 \\ 0 & D^* \end{pmatrix} \begin{pmatrix} \overline{U} & \overline{V} \\ \overline{V} & \overline{U} \end{pmatrix} \begin{pmatrix} C & 0 \\ 0 & C^* \end{pmatrix} \tag{2.61}$$

where D and C are unitary matrices and $\overline{U}$ and $\overline{V}$ are real matrices, which have a particular blocked form, expressed through the coefficents u_k, v_k; the reader may refer to appendix **??** for the explicit representation. We can also define the matrices U, V as

$$U = D\overline{U}C, \quad V = D^*\overline{V}C. \tag{2.62}$$

Using the decomposition (2.61) we can define the *canonical basis* as

$$a_k^\dagger = \sum_l D_{lk}^\dagger c_l^\dagger, \tag{2.63}$$

a *special Bogoliubov transformation* between *paired* levels as

$$\alpha_k^\dagger = u_k a_k^\dagger - v_k a_{\tilde{k}}, \tag{2.64}$$

$$\alpha_{\tilde{k}}^\dagger = u_k a_{\tilde{k}}^\dagger + v_k a_k, \tag{2.65}$$

and *blocked* levels

$$\alpha_i = a_i, \quad \alpha_n^\dagger = a_n^\dagger \tag{2.66}$$

$$\alpha_i = a_i^\dagger, \quad \alpha_n = a_n, \tag{2.67}$$

where $u_k = u_{\tilde{k}}$, $v_k = -v_{\tilde{k}}$, and a unitary transformation of the quasi-particle operators $\alpha_k^\dagger$ among themselves

$$\beta_k^\dagger = \sum_{k'} C_{k'k} a_{k'}^\dagger. \tag{2.68}$$

We are now able to define the Bogoliubov ground state $|\mathrm{HFB}\rangle$, as the one for which

$$\beta_k |\mathrm{HFB}\rangle = 0 \ \forall k = 1, \dots, M \tag{2.69}$$

where M is determined by the physical situation [43]. The wavefunction that satisfies this condition reads

$$|\mathrm{HFB}\rangle = \prod_k^M \beta_k |-\rangle. \tag{2.70}$$

We can define the pairing tensor as

$$\kappa_{ll'} = \langle \mathrm{HFB}| c_{l'} c_l |\mathrm{HFB}\rangle, \tag{2.71}$$

which in matrix form reads, alongside the density matrix

$$\kappa = V^* U^T, \quad \rho = V^* V^T. \tag{2.72}$$

We can now apply the variational principle (2.6)

$$\delta \frac{\langle \mathrm{HFB}| \hat{H} - \lambda \hat{N} |\mathrm{HFB}\rangle}{\langle \mathrm{HFB}|\mathrm{HFB}\rangle} = 0. \tag{2.73}$$

which yields the eigenvalue problem

$$\begin{pmatrix} h - \lambda & \Delta \\ -\Delta^* & -(h-\lambda)^* \end{pmatrix} \begin{pmatrix} U_k \\ V_k \end{pmatrix} = \mathcal{H}_{\mathrm{HFB}} \begin{pmatrix} U_k \\ V_k \end{pmatrix} = E_k \begin{pmatrix} U_k \\ V_k \end{pmatrix}, \tag{2.74}$$

Here, h is the single-particle Hamiltanian, which reads

$$h_{kk'} = t_{kk'} + \Gamma_{kk'}, \tag{2.75}$$

where $\Gamma_{kk'}$ is the mean field potential, given by

$$\Gamma_{kk'} = \sum_{ll'} \overline{v}_{kl'k'l} \rho_{ll'} \tag{2.76}$$

and the pairing field Δ reads

$$\Delta_{kk'} = \sum_{ll'} \overline{v}_{kk'll'} \kappa_{ll'}. \tag{2.77}$$

In the canonical basis, we are able to solve for the occupation numbers

$$u_k^2 = \frac{1}{2} \left(1 + \frac{h_{kk} + h_{\tilde{k}\tilde{k}}}{\sqrt{(h_{kk} + h_{\tilde{k}\tilde{k}})^2 + 4\Delta_{k\tilde{k}}}} \right) \tag{2.78}$$

where $v_k^2 = 1 - u_k^2$ is guaranteed by the unitarity of the matrices. Starting from an initial guess, we solve the eigenvalue problem (2.74), we extract the occupation numbers (2.78), use them to build the new mean field (2.76) and pairing field (2.77), and repeat the process until convergence.

HFB quasi-particle spectrum Let us assume that $\Psi = (U, V)^T$ is a solution of equation (2.74) with eigenvalue E

$$\mathcal{H}_{\mathrm{HFB}} \Psi = E\Psi. \tag{2.79}$$

Let the particle-hole matrix $\mathcal{C}$ be defined as

$$\mathcal{C} = \begin{pmatrix} 0 & I \\ I & 0 \end{pmatrix}, \tag{2.80}$$

it's trivial to show that

$$\mathcal{C}\mathcal{H}_{\mathrm{HFB}}\mathcal{C} = -\mathcal{H}_{\mathrm{HFB}}^*, \tag{2.81}$$

and

$$\mathcal{C} = \mathcal{C}^{-1} \implies \mathcal{C}\mathcal{H}_{\mathrm{HFB}} = -\mathcal{H}_{\mathrm{HFB}}\mathcal{C}. \tag{2.82}$$

If we take the complex conjugate of equation (2.79), we get

$$\mathcal{H}_{\text{HFB}}^* \Psi^* = E\Psi^*, \tag{2.83}$$

if we multiply both sides on the left by $\mathcal{C}$ and use (2.82), we get

$$-\mathcal{H}_{\text{HFB}}\mathcal{C}\Psi^* = E\mathcal{C}\Psi^*, \tag{2.84}$$

$$\mathcal{H}_{\text{HFB}}\mathcal{C}\Psi^* = -E\mathcal{C}\Psi^*, \tag{2.85}$$

meaning that $\mathcal{C}\Psi^*$ is a solution of the eigenvalue problem (2.74) as well, with eigenvalue $-E$, hence for every quasi-particle energy we have a corresponding opposite-sign one; moreover, it can be proven that the HFB hamiltonian is unbounded, both from below and above [41]. This feature poses a challenge for numerical solutions of the HFB problem, as we shall see in chapter 3.

2.3. Skyrme

Now that the theoretical framework is clear, we can use the Skyrme microscopic effective interaction to do nuclear structure calculations.

2.3.1. Skyrme force

It was first proposed by Tony Skyrme in 1958 [48] as a zero range force between nucleons, comprising a two body attractive term that reads

$$\begin{aligned}
v^{(2)}(\mathbf{r}_1, \mathbf{r}_2) = {} & t_0 \left(1 + x_0 P_\sigma\right) \delta(\mathbf{r}) \\
& + \frac{1}{2} t_1 \left(1 + x_1 P_\sigma\right) \left[\mathbf{P}'^2 \delta(\mathbf{r}) + \delta(\mathbf{r})\mathbf{P}^2\right] \\
& + t_2 P_\sigma \mathbf{P}' \cdot \delta(\mathbf{r})\mathbf{P} \\
& + iW_0 \boldsymbol{\sigma} \cdot \left[\mathbf{P}' \times \delta(\mathbf{r})\mathbf{P}\right]
\end{aligned}$$

and a three body term, that is

$$v^{(3)}(\boldsymbol{r}_1, \boldsymbol{r}_2, \boldsymbol{r}_3) = t_3 \delta(\boldsymbol{r}_1 - \boldsymbol{r}_2)\delta(\boldsymbol{r}_2 - \boldsymbol{r}_3)$$

which mimics the repulsive three-body force; without it, a collapse of the nuclear density would occur. The different operators are defined as

$$\mathbf{r} = \mathbf{r}_1 - \mathbf{r}_2 \quad \mathbf{R} = \frac{\mathbf{r}_1 + \mathbf{r}_2}{2} \tag{2.86}$$

which are respectively the relative position of two particles and their center of mass coordinate, assuming equal masses.

$$\mathbf{P} = \frac{-i(\nabla_1 - \nabla_2)}{2} \tag{2.87}$$

which is the so called relative wave-number operator, corresponding to the relative momentum of the two interacting particles.

$$\boldsymbol{\sigma} = \boldsymbol{\sigma}_1 + \boldsymbol{\sigma}_2 \tag{2.88}$$

being the total spin of the two interacting particles, and lastly

$$\mathbf{P}_\sigma = \frac{(1 + \boldsymbol{\sigma}_1 \cdot \boldsymbol{\sigma}_2)}{2} \tag{2.89}$$

which represents the spin-exchange operator. Primed operators refer to the adjoint acting on the left.

It's trivial to show that the three-body term, in the case of even-even nuclei, is equivalent to a two-body, density-dependent interaction [52]

$$v^{(3)}(\boldsymbol{r}_1, \boldsymbol{r}_2) = \frac{1}{6}t_3(1 + P_\sigma)\delta(\boldsymbol{r})\rho(\boldsymbol{R}) \tag{2.90}$$

The zero-range feature is apparent in the choice of the Dirac delta $\delta(\mathbf{r})$, which allows the writing of the Fock term detailed in (2.17) as a purely local one.

Modern parametrization

The Skyrme force has evolved from the original one to accomodate new nuclei and properties, done through the addition of a few parameters, yielding the following form of the

interaction [9]

$$v^{(2)}(\mathbf{r}_1, \mathbf{r}_2) = t_0 \left(1 + x_0 P_\sigma\right) \delta(\mathbf{r})$$

$$+ \frac{1}{2} t_1 \left(1 + x_1 P_\sigma\right) \left[\mathbf{P}'^2 \delta(\mathbf{r}) + \delta(\mathbf{r})\mathbf{P}^2\right]$$

$$+ t_2 \left(1 + x_2 P_\sigma\right) \mathbf{P}' \cdot \delta(\mathbf{r})\mathbf{P}$$

$$+ \frac{1}{6} t_3 \left(1 + x_3 P_\sigma\right) [\rho(\mathbf{R})]^\sigma \delta(\mathbf{r})$$

$$+ iW_0 \boldsymbol{\sigma} \cdot \left[\mathbf{P}' \times \delta(\mathbf{r})\mathbf{P}\right]$$

$$+ \frac{1}{6} t_3 \left(1 + x_3 P_\sigma\right) [\rho(\mathbf{R})]^\sigma \delta(\mathbf{r})$$

Here, the boundary between Hartree-Fock and DFT starts to thin out, as the exponent σ of the density makes that piece of the force a true three-body interaction only for the value $\sigma = 1$ [18]. On top of that, additional, empirical tuning of the resulting energy density needed to reach satisfactory physical accuracy, such as the case for the spin-orbit couplings [42], prompts for the following, well established proceeding: use the Skyrme interaction to obtain the Hamiltonian density

$$\langle H \rangle = \langle \Psi | H | \Psi \rangle = \int \mathcal{H}(\boldsymbol{r}) d\mathbf{r} \tag{2.91}$$

and use it as a starting point to build an energy density functional and employ DFT.

2.3.2. Energy density functional

The energy functional to be minimized is of the form [2]

$$E_{\mathrm{HF}} = E_{\mathrm{Kin}} + E_{\mathrm{Skyrme}} + E_{\mathrm{Coul}} = \int (\mathcal{E}_{\mathrm{Kin}} + \mathcal{E}_{\mathrm{Skyrme}} + \mathcal{E}_{\mathrm{Coul}}) d\boldsymbol{r}. \tag{2.92}$$

Densities

Functional (2.92) can be expressed through a series of particle densities. Let us define them and express them on the spin coordiantes up ($\uparrow$) and down ($\downarrow$) for the convinience in a mesh representation.

The starting point is the density matrix, defined as

$$\rho_q(\mathbf{r}\sigma, \mathbf{r}\sigma') = \sum_\alpha \phi_{\alpha,\sigma}(\mathbf{r})\phi^*_{\alpha,\sigma'}(\mathbf{r}') \tag{2.93}$$

where the index α goes through all single particle states of the particles of type q (protons, neutrons) and the index σ refers to the spin coordinate. The particle density is defined

as

$$\rho_q(\mathbf{r}) := \rho_q(\mathbf{r}, \mathbf{r}')\Big|_{\mathbf{r}=\mathbf{r}'} := \sum_\sigma \rho(\mathbf{r}\sigma, \mathbf{r}'\sigma)\Big|_{\mathbf{r}=\mathbf{r}'} = \sum_\alpha \phi_\uparrow(\mathbf{r})\phi_\uparrow^*(\mathbf{r}') + \phi_\downarrow(\mathbf{r})\phi_\downarrow^*(\mathbf{r}')\Big|_{\mathbf{r}=\mathbf{r}'}$$

$$= \sum_\alpha |\phi_\uparrow(\mathbf{r})|^2 + |\phi_\downarrow(\mathbf{r})|^2. \tag{2.94}$$

The kinetic density reads

$$\tau_q(\mathbf{r}) := \sum_\alpha \nabla' \cdot \nabla \rho_q(\mathbf{r}, \mathbf{r}')\Big|_{\mathbf{r}'=\mathbf{r}}$$

$$= \sum_{\sigma,\alpha} \nabla\phi_\sigma(\mathbf{r}) \cdot \nabla\phi_\sigma^*(\mathbf{r}')\Big|_{\mathbf{r}=\mathbf{r}'} = \sum_{\sigma,\alpha} |\nabla\phi_\sigma(\mathbf{r})|^2$$

$$= \sum_\alpha |\nabla\phi_\uparrow(\mathbf{r})|^2 + |\nabla\phi_\downarrow(\mathbf{r})|^2. \tag{2.95}$$

The spin density reads

$$s_q(\mathbf{r}, \mathbf{r}') := \sum_{\sigma\sigma',i} \rho_q(\mathbf{r}\sigma, \mathbf{r}'\sigma') \langle\sigma'| \hat{\boldsymbol{\sigma}} |\sigma\rangle = \sum_\alpha \begin{bmatrix} \phi_\uparrow^*(\mathbf{r}') & \phi_\downarrow^*(\mathbf{r}') \end{bmatrix} \hat{\boldsymbol{\sigma}} \begin{bmatrix} \phi_\uparrow(\mathbf{r}) \\ \phi_\downarrow(\mathbf{r}) \end{bmatrix} \tag{2.96}$$

and lastly, the spin-orbit density tensor reads

$$J_{q,\mu\nu} := \frac{1}{2i}(\partial_\mu - \partial_\mu')s_{q,\nu}(\mathbf{r}, \mathbf{r}')\Big|_{\mathbf{r}'=\mathbf{r}}$$

$$= \frac{1}{2i}\left(\begin{bmatrix} \phi_\uparrow^*(\boldsymbol{r}') & \phi_\downarrow^*(\boldsymbol{r}') \end{bmatrix} \partial_\mu\hat{\sigma}_\nu \begin{bmatrix} \phi_\uparrow(\boldsymbol{r}) \\ \phi_\downarrow(\boldsymbol{r}) \end{bmatrix} - \begin{bmatrix} \phi_\uparrow(\boldsymbol{r}) & \phi_\downarrow(\boldsymbol{r}) \end{bmatrix} \partial_\mu'\hat{\sigma}_\nu \begin{bmatrix} \phi_\uparrow^*(\boldsymbol{r}') \\ \phi_\downarrow^*(\boldsymbol{r}') \end{bmatrix} \right)_{\mathbf{r}'=\mathbf{r}}$$

$$= \sum_\alpha \text{Im}\left\{ \begin{bmatrix} \phi_\uparrow^*(\boldsymbol{r}) & \phi_\downarrow^*(\boldsymbol{r}) \end{bmatrix} \partial_\mu\hat{\sigma}_\nu \begin{bmatrix} \phi_\uparrow(\boldsymbol{r}) \\ \phi_\downarrow(\boldsymbol{r}) \end{bmatrix} \right\} \tag{2.97}$$

which also defines the spin-orbit current vector $\boldsymbol{J}$ that reads

$$J_{q,\kappa}(\boldsymbol{r}) = \sum_{\mu\nu} \epsilon_{\kappa\mu\nu} J_{q,\mu\nu}(\boldsymbol{r}). \tag{2.98}$$

Kinetic functional

The kinetic term can be expressed as

$$\mathcal{E}_{\text{Kin}} = \frac{\hbar^2}{2m}\tau \tag{2.99}$$

which is found integrating by parts (2.36).

Skyrme functional

Since this work only deals with even-even nuclei, only time-even densities, which are the ones previously defined, are non-vanishing, due to the ground state being time-reversal invariant [2]. This reduces the Skyrme functional to the following form [50]

$$\mathcal{E}_{\text{Skyrme}} = \sum_{t=0,1} \left\{ C_t^\rho[\rho_0]\rho_t^2 + C_t^{\Delta\rho}\rho_t\nabla^2\rho_t + C_t^{\nabla\cdot J}\rho_t\nabla\cdot\mathbf{J}_t + C_t^\tau\rho_t\tau_t \right\} \tag{2.100}$$

where

$$C_0^\rho = +\frac{3}{8}t_0 + \frac{3}{48}t_3\rho_0^\sigma \tag{2.101}$$

$$C_1^\rho = -\frac{1}{8}t_0(1+2x_0) - \frac{1}{48}t_3(1+x_3)\rho_0^\sigma \tag{2.102}$$

$$C_0^\tau = +\frac{3}{16}t_1 + \frac{1}{16}t_2(5+4x_2) \tag{2.103}$$

$$C_1^\tau = -\frac{1}{16}t_1(1+2x_1) + \frac{1}{16}t_2(1+2x_2) \tag{2.104}$$

$$C_0^{\Delta\rho} = -\frac{9}{64}t_1 + \frac{1}{64}t_2(5+4x_2) \tag{2.105}$$

$$C_1^{\Delta\rho} = +\frac{3}{64}t_1(1+2x_1) + \frac{1}{64}t_2(1+2x_2) \tag{2.106}$$

$$C_0^{\nabla\cdot J} = -\frac{3}{4}W_0 \tag{2.107}$$

$$C_1^{\nabla\cdot J} = -\frac{1}{4}W_0. \tag{2.108}$$

Here, $t = 0, 1$ refers to the isoscalar and isovector components of the densities, eg

$$\rho_0 = \rho_p + \rho_n$$

$$\rho_1 = \rho_p - \rho_n.$$

We can now derive the Kohn-Sham equations, by minimizing the functional under the constraint

$$\langle\varphi_i|\varphi_j\rangle = \delta_{ij}. \tag{2.109}$$

The resulting Kohn-Sham equations are of the form

$$\left[-\nabla\left(\frac{\hbar^2}{2m_q^*(\mathbf{r})}\nabla\right) + U_q(\mathbf{r}) + \delta_{\text{q,proton}}U_C(\mathbf{r}) - i\mathbf{B}_q(\mathbf{r})\cdot(\nabla\times\boldsymbol{\sigma}) \right]\varphi_\alpha = \varepsilon_\alpha\varphi_\alpha \tag{2.110}$$

where an effective mass field arises, which is defined as

$$\frac{\hbar^2}{2m_q^*(\mathbf{r})} = \frac{\delta\mathcal{E}}{\delta\tau_q} \tag{2.111}$$

a mean field potential, which reads

$$U_q(\mathbf{r}) = \frac{\delta\mathcal{E}}{\delta\rho_q} \tag{2.112}$$

and a spin-orbit field, given by

$$\mathbf{B}_q(\mathbf{r}) = \frac{\delta\mathcal{E}}{\delta\mathbf{J}_q}. \tag{2.113}$$

The coulomb field U_C, which is present only in the single particle equation for protons, doesn't come from the Skyrme interaction, rather from the Coulomb part of the whole functional. It will be properly derived in section 2.4.

Following the rules for functional derivatives, outlined in the appendix A.3 we get

$$\begin{aligned}
\frac{\hbar^2}{2m_q^*(\mathbf{r})} = &+ \frac{\hbar^2}{2m} \\
&+ \frac{1}{8}[t_1(2+x_1) + t_2(2+x_2)]\rho(\mathbf{r}) \\
&- \frac{1}{8}[t_1(1+2x_1) + t_2(1+2x_2)]\rho_q(\mathbf{r})
\end{aligned} \tag{2.114}$$

$$\begin{aligned}
U_q(\mathbf{r}) = &+ \frac{1}{8}[t_1(2+x_1) + t_2(2+x_2)]\rho \\
&+ \frac{1}{8}[t_2(1+2x_2) - t_1(1+2x_1)]\rho_q \\
&+ \frac{1}{8}[t_1(2+x_1) + t_2(2+x_2)]\tau \\
&+ \frac{1}{8}[t_2(1+2x_2) - t_1(1+2x_1)]\tau_q \\
&+ \frac{1}{16}[t_2(2+x_2) - 3t_1(2+x_1)]\nabla^2\rho \\
&+ \frac{1}{16}[3t_1(2x_1+1) + t_2(2x_2+1)]\nabla^2\rho_q
\end{aligned} \tag{2.115}$$

$$\begin{aligned}
\mathbf{B}_q(\mathbf{r}) = &+ \frac{1}{2}W_0[\nabla\rho + \nabla\rho_q] \\
&- \frac{1}{8}(t_1 x_1 + t_2 x_2)\mathbf{J} + \frac{1}{8}(t_1 - t_2)\mathbf{J}_q.
\end{aligned} \tag{2.116}$$

Unless otherwise specified, unlabelled densities denote isoscalar quantities (sum of neutron and proton).

2.3.3. Funcitonals

WRITE ABOUT DIFFERENT FUNCTIONALS FITS.

2.4. Coulomb interaction

Unlike the Skyrme interaction, the Coulomb force is finite-range, giving rise to an unwanted integral operator in the single-particle Hamiltonian. A well known and widely used device is the Slater approximation [22], which gives a local exchange interaction. In this approximation, the Coulomb energy reads

$$E_{\text{Coul}} = \int \mathcal{E}_{\text{Coul}}(\mathbf{r}) d\boldsymbol{r}$$

where the energy density is given by

$$\mathcal{E}_{\text{Coul}}(\boldsymbol{r}) = \frac{e^2}{2} \left[\int \frac{\rho_p(\mathbf{r})\rho_p(\mathbf{r}')}{|\mathbf{r} - \mathbf{r}'|} d\mathbf{r}' - \frac{3}{2} \left(\frac{3}{\pi} \right)^{\frac{1}{3}} \rho_p^{4/3}(\mathbf{r}) \right]. \tag{2.117}$$

which results in the Coulomb potential field

$$U_C(\mathbf{r}) = \frac{\delta \mathcal{E}_{\text{Coul}}}{\delta \rho_p} = \frac{e^2}{2} \left[\int \frac{\rho_p(\mathbf{r}')}{|\mathbf{r} - \mathbf{r}'|} d^3\mathbf{r}' - 2 \left(\frac{3}{\pi} \right)^{\frac{1}{3}} \rho_p^{1/3}(\mathbf{r}) \right] \tag{2.118}$$

where the first term is the direct Coulomb interaction, which simply is the Coulomb energy generated by the proton density, while the second term is the exchange Coulomb interaction, which is local and depends on the proton density through a power factor of 1/3. From a computational standpoint, the exchange part is trivial, while the direct one is more involved. One could compute the integral, but the complexity on a 3D mesh grows as $\mathcal{O}(N^6)$, where N is the total number of points on the mesh, rendering it unfeasible for fine calculations.

An alternative approach is to solve the Poisson equation (from now on, V_c refers to the direct part only)

$$\nabla^2 V_c = 4\pi e^2 \rho_p. \tag{2.119}$$

Given the proton density, we can impose Dirichlet boundary conditions, which can be extracted from a quadrupole expansion of the charge density [27]

$$V_c(\mathbf{r}) = 4\pi e^2 \sum_{\lambda=0}^{2} \sum_{\mu=-\lambda}^{\lambda} \frac{\langle Q_{\lambda\mu} \rangle Y_{\lambda\mu}}{r^{1+\lambda}} \quad \text{on } \partial\Omega \tag{2.120}$$

where $\langle Q_{\lambda\mu} \rangle$ is defined as

$$\langle Q_{\lambda\mu} \rangle = \int r^\lambda Y_{\lambda\mu}^*(\mathbf{r}) \rho_p(\mathbf{r}) d^3\mathbf{r} \tag{2.121}$$

Since we expect a charge density confined to the nuclear shape, higher order terms in the expansion can be neglected, provided that the box is sufficiently large.

In a reference frame where the nucleus center of mass is at the origin, the expansion reduces to

$$V_c(\mathbf{r}) = \frac{Ze^2}{r} + e^2 \sum_{\mu=-2}^{2} \frac{\langle Q_{2\mu} \rangle Y_{2\mu}}{r^3} \quad \text{on } \partial\Omega. \tag{2.122}$$

The reader can refer to appendix A.1 for the definition and numerical evaluation of the spherical harmonics $Y_{\lambda\mu}$.

2.5. Energy calculation

One, if not the most important physical quantity we want to compute is the total energy of the system.

Integrated energy

The obvious way would be to evaluate the functional for a given density. We will call this *integrated energy*.

$$E_{\text{int}} = E[\rho, \tau, J_{\mu\nu}] = \int \mathcal{E} d\mathbf{r}$$

Hartree-Fock energy

An alternative approach can be used, as in a stationary point $\delta E = 0$, the single particle eigenvalue equation (2.110) stands true, summarized as

$$(t + U)\varphi_k = \varepsilon_k \varphi_k \tag{2.123}$$

We can multiply (2.123) on the left by φ_k^* and integrate to get

$$\int -\varphi_k^* \frac{\hbar^2}{2m} \nabla^2 \varphi_k d\boldsymbol{r} + \int \varphi_k^* U \varphi_k d\boldsymbol{r} = \int \varphi_k^* \varepsilon_k \varphi_k d\boldsymbol{r} \tag{2.124}$$

The integral on the right hand side of (2.124) evaluates to ε_k due to the orthonormality constraint. If we sum over all states k we get

$$\sum_k \left\{ \int -\varphi_k^* \frac{\hbar^2}{2m} \nabla^2 \varphi_k d\boldsymbol{r} + \int \varphi_k^* U \varphi_k d\boldsymbol{r} \right\} = \sum_k \varepsilon_k \tag{2.125}$$

$$\sum_k t_k + \int \rho U = \sum_k \varepsilon_k \tag{2.126}$$

Since U is calculated as the functional derivative with respect to the density ρ (2.112), assuming that the functional has a power dependence from ρ of the form $\mathcal{E}_{\text{Skyrme}} = A\rho^{\sigma+1}$ as in our case, we get the *rearrangement energy*

$$\rho U = \rho \frac{\delta \mathcal{E}_{\text{Skyrme}}}{\delta \rho} = \rho(1+\sigma)A\rho^\sigma = (1+\sigma)A\rho^{\sigma+1} = \mathcal{E}_{\text{Skyrme}} + \sigma\mathcal{E}_{\text{Skyrme}} = \mathcal{E}_{\text{Skyrme}} - \mathcal{E}_{\text{rea}}$$

$$\tag{2.127}$$

If we explicit ρU in equation (2.126) using (2.127), we get to

$$\sum_k t_k + \int (\mathcal{E}_{\text{Skyrme}} - \mathcal{E}_{\text{rea}})d\boldsymbol{r} = \sum_k \varepsilon_k$$

Isolating the Skyrme energy density

$$\int \mathcal{E}_{\text{Skyrme}} d\boldsymbol{r} = \sum_k (\varepsilon_k - t_k) + \int \mathcal{E}_{\text{rea}} d\boldsymbol{r} \tag{2.128}$$

and given the total energy of the system from (**??**)

$$E = \sum_k t_k + \frac{1}{2} \int \mathcal{E}_{\text{Skyrme}} d\boldsymbol{r} \tag{2.129}$$

substituting (2.128) in (2.129) yields

$$E_{\text{HF}} = \frac{1}{2} \sum_k (\varepsilon_k + t_k) + \int \mathcal{E}_{\text{rea}} d\boldsymbol{r} = \frac{1}{2} \left(T + \sum_k \varepsilon_k \right) + E_{\text{rea}} \tag{2.130}$$

which will is called *Hartree-Fock energy*.

Sidenote The actual functional, including the Coulomb exchange term, has different ρ terms, which can be summarized as

$$\mathcal{E}_{\text{Skyrme}} = \sum_j A_j \rho^{\sigma_j + 1} \implies E_{\text{rea}} = -\sum_j \sigma_j A_j \rho^{\sigma_j + 1}$$

This means that only terms with a $\sigma_j \neq 0, -1$ actually contribute to the rearrangement energy.

Since equation (2.130) is valid only for $\delta E = 0$, it's useful to check its equivalence with the integrated energy at convergence, so one can be sure to actually be in a stationary point.

3 | Numerical methods

This chapter is devoted to describing the practical implementation of the nuclear Hartree-Fock method of this work. In section 3.1, the two partial differential equations (PDEs) of interest, the Kohn-Sham equation and the Poisson equation, are numerically approximated through finite differences. In section 3.2.2, a breakdown of numerical solvers for the large-scale eigenvalue problem posed by the KS equation is presented, to pedagogically illustrate the rationale and implementation of the GCG algorithm. Finally, in section 3.3, the self-consistent calculation is presented, along with the implementation of spatial constraints and the optimization of the numerical parameters of GCG.

3.1. Finite differences

The framework used to numerically solve the relevant PDEs of the problem, is the one of finite differences. The core idea is to discretize the domain on a 3D mesh, use Taylor expansions to approximate differential operators and then solve the resulting system of linear equations.

3.1.1. 3D mesh

The first step of the process is representing the different fields in a numerical, discretized fashion. Generally speaking, we deal at most with 2-rank tensors, which depend on three space coordinates and one spin coordinate.

Discretizing the 3D cartesian space with a 3-index mesh, choosing a box whose size along x, y, z is respectively $[-a_x, a_x]$, $[-a_y, a_y]$, $[-a_z, a_z]$, and a number of points n_x, n_y, n_z, the resulting lattice will be given by

$$V = \{(-a_x + ih_x, -a_y + ih_y, -a_z + ih_z)\} = \{(x_i, y_j, z_k)\}$$

Where the indices and step sizes are

$$i = 0, \ldots, n_x - 1 \quad h_x = \frac{2a_x}{n_x - 1}$$

$$j = 0, \ldots, n_y - 1 \quad h_y = \frac{2a_y}{n_y - 1}$$

$$k = 0, \ldots, n_z - 1 \quad h_z = \frac{2a_z}{n_z - 1}$$

The following implementation assumes $a = a_x = a_y = a_z = a$ and $n = n_x = n_y = n_z = n$, without losing generality.

Including the spin degree of freedom, we can finally represent the fields in a numerical way through

$$\varphi(\boldsymbol{r}, \sigma) \mapsto \varphi(x_i, y_j, z_k, s) = \varphi_{ijks} \tag{3.1}$$

Differential operators discretization

By using Taylor series, it's possible to write approximations to derivatives [56], in any point of the lattice, of any (reasonable) order of accuracy, involving only near neighbouring points. In the present work, 5-points derivatives are used, meaning Taylor expansions are written for $\varphi(x \pm h)$ and $\varphi(x \pm 2h)$ to compute the differential operators. Formulae for first and second derivates are given in appendix A.2.

From the theory background of chapter 2, we discern two main kinds of PDEs: the Schrödinger-like KS equation, and the Poisson equation.

3.1.2. Schrödinger equation

Starting from the Schrödinger equation (2.110), reported here for clarity

$$\left[-\nabla \left(\frac{\hbar^2}{2m_q^*(\mathbf{r})} \nabla \right) + U_q(\mathbf{r}) + \delta_{\text{q,proton}} U_C(\mathbf{r}) - i\mathbf{B}_q(\mathbf{r}) \cdot (\nabla \times \boldsymbol{\sigma}) \right] \varphi = \varepsilon \varphi$$

it can be compactly written as

$$f(\nabla^2 \varphi, \nabla \varphi, \varphi, \boldsymbol{r}, s) = \varepsilon \varphi. \tag{3.2}$$

If f is linear in φ, it is be possible to rewrite it as a linear combination of the values of φ on the mesh, after which we can use linear algebra methods to solve the problem.

Linearity   Breaking down each part of the equation, the kinetic term

$$\nabla\left(\frac{\hbar^2}{2m_q^*(\mathbf{r})}\nabla\right)\varphi = \frac{\hbar^2}{2m_q^*(\mathbf{r})}\nabla^2\varphi + \nabla\left(\frac{\hbar^2}{2m_q^*(\mathbf{r})}\right)\cdot\nabla\varphi \tag{3.3}$$

is evidently linear in φ.

The spin-orbit term of (2.110), which we write as

$$\hat{h}_{\mathrm{SO}} = -i\mathbf{B}_q(\boldsymbol{r})\cdot(\nabla\times\boldsymbol{\sigma})$$
$$= -i[\mathbf{B}_{q,x}(\boldsymbol{r})(\sigma_z\partial_y - \sigma_y\partial_z) + \mathbf{B}_{q,y}(\boldsymbol{r})(\sigma_x\partial_z - \sigma_z\partial_x) + \mathbf{B}_{q,z}(\boldsymbol{r})(\sigma_y\partial_x - \sigma_x\partial_y)]$$

is also linear in φ.

Finally, the mean field terms U_q, U_c

$$(U_q + \delta_{\mathrm{q,proton}}U_c)\varphi$$

are just multiplicative, hence linear.

Given that the whole equation is linear in φ, we can evaluate it on the chosen mesh, using finite differences to approximate the differential operators, yielding a linear eigenvalue problem of the form

$$\sum_{\alpha=1}^{N} A_{\alpha\beta}\varphi_\beta = E\varphi_\alpha \tag{3.4}$$

where the shorthand notation $N = 2\cdot N_x\cdot N_y\cdot N_z$ is used to denote the size of the matrix A, which is $N\times N$.

Boundary conditions

We expect the nucleus to be a localized object, leading to vanishing Dirichlet boundary conditions for the Schrödinger equation. Near the boundaries, the derivatives will involve points outside the box and setting these points to zero, is equivalent to solving

$$\begin{bmatrix} 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & A & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix}\begin{bmatrix} \varphi_{-2} \\ \varphi_{-1} \\ \varphi \\ \varphi_N \\ \varphi_{N+1} \end{bmatrix} = E\begin{bmatrix} \varphi_{-2} \\ \varphi_{-1} \\ \varphi \\ \varphi_N \\ \varphi_{N+1} \end{bmatrix} \tag{3.5}$$

From this system of equations, we get for points outside the boundary:

$$\begin{cases} \varphi_{-2} = 0 \\ \varphi_{-1} = 0 \\ \dots \end{cases} \tag{3.6}$$

Meaning that φ outside the box will automatically be set to zero if the A matrix is built assuming those points to be zero when computing its coefficients.

3.1.3. Poisson equation

The other fundamental PDE we need to solve is the Poisson equation encountered in section 2.4. Dropping the c and p subscripts, it reads

$$\nabla^2 V = 4\pi e^2 \rho$$

It's simpler than the Schrödinger equation, as it only involves a Laplacian and it's not an eigenvalue problem. The right is side is given, and the solution is found by inverting the coefficients' matrix.

Boundary conditions

Unlike the Schrödinger equation, we do not expect the solution to rapidly decay near the boundaries; as reported in section 2.4, we have fixed, non-vanishing boundary conditions, which we have to properly impose on the system.

We can choose a direction, say x, and look at the discretized equation at the boundaries $x = \pm a$. Since the indices j, k won't vary, we can omit them, and ignore the other derivates in the following equations.

$$\begin{aligned} \nabla^2 V &= \partial_{xx} V + \partial_{yy} V + \partial_{zz} V \\ &= \frac{-V_{i-2} + 16V_{i-1} - 30V_i + 16V_{i+1} - V_{i+2}}{12h^2} + \dots = 4\pi e^2 \rho_i \end{aligned} \tag{3.7}$$

Near a boundary, say $i = 0$, the formula calls for points outside the box, known as *ghost points*. Since they are not part of the linear system, but they are known, we can bring them on the right side of equation (3.7).

$$\frac{-30V_0 + 16V_1 - V_2}{12h^2} = 4\pi e^2 \rho_0 + \frac{V_{-2} - 16V_{-1}}{12h^2} = \tilde{\rho}_0 \tag{3.8}$$

The same procedure must be applied to all equations involving ghost points, e.g. for $i = 1$

$$\frac{+16V_0 - 30V_1 + 16V_2 - V_3}{12h^2} = 4\pi e^2 \rho_1 + \frac{V_{-1}}{12h^2} = \tilde{\rho}_1. \tag{3.9}$$

The proper system to solve will then be

$$AV = \tilde{\rho} \tag{3.10}$$

Where A is constructed as previously specified. Solving with $\tilde{\rho}$ on the right hand side will force the solution to obey boundary conditions.

On higher order approximations and performance

Higher and higher order approximations for derivatives involve more points that are further away. This increases accuracy by reducing the finite differences error, but it also decreases the matrix sparseness.

3.2. Eigenvalue problem

This section is devoted to the approximate solution of the eigenvalue problem, needed for the Schrödinger equation (2.110).

Eigenvalue problems are ubiquitous in physics and engineering, and while solving one for a small matrix is trivial, it still requires roughly $O(n^3)$ operations [21] to do so. More often than not, real computational applications result in large-scale matrices, which are completely out of question for exact eigenvalues calculations, thus requiring the use of approximate algorithms.

We will begin by describing common building blocks of iterative eigensolvers in section 3.2.1, namely:

- the approximate solutions of linear systems by the use of the Conjugate Gradient method;

- matrix preconditioning to speed up convergence;

- the Rayleigh-Ritz procedure to find good approximations to the eigenpairs in a certain subspace; and

- the shift-and-invert method, to select the desired portion of the eigenvalue spectrum.

After describing these building blocks, some of the most commonly used eigensolvers are described in section 3.2.2, focusing on the core ideas and stating their limitations, to

finally address the General Conjugate Gradient method, whose implementation in the present work is detailed in section 3.2.3.

3.2.1. Conjugate Gradient and numerical techniques

Conjugate Gradient method

Solving linear systems of the form

$$Ax = b \tag{3.11}$$

is crucial in many eigensolvers. The Conjugate Gradient (CG) is perhaps the most famous iterative solver in this sense, especially in regards to sparse matrices, as we will see in a moment. CG applies to cases where A is a real, $n \times n$, positive-definite, symmetric matrix, and x and b are n-dimensional vectors.

Many generalizations to this method exist, which relax the requirements on the matrix, like BiCGSTAB, CGRES and so on [45]. We will describe the working principle of CG, but the same applies to all the others, with slight variations.

Steepest descent method   The quadratic form $f(x)$ derived from the system (3.11) is

$$f(x) = \frac{1}{2}x^T A x - b^T x \tag{3.12}$$

If A is symmetric, positive-definite, the shape of $f(x)$ is convex and has a global minimum for

$$\nabla_x f(x) = Ax_m - b = 0 \implies Ax_m = b, \tag{3.13}$$

hence the extremum of the quadratic form is the also the solution of the linear system (3.11).

We can employ the well-known gradient descent technique [47] to find such point: starting from a guess x_0, we compute the direction where f decreases the most (the residual r_i), compute the step size for maximal decrease, and update x_i at each iteration accordingly, repeating until convergence.

$$d_i = r_i = = b - Ax_i \tag{3.14}$$

$$x_{i+1} = x_i + \alpha_i r_i \tag{3.15}$$

$$\text{with } \alpha_i \text{ such that } \frac{\mathrm{d}f}{\mathrm{d}\alpha_i} = 0 \implies \alpha_i = \frac{r_i^T r_i}{r_i^T A r_i} \tag{3.16}$$

This is a powerful but highly inefficient procedure. We are not ensuring that the search direction doesn't end up with components in subspaces that were explored already.

It can be proven [47] that the norm of the error $e_i = x_i - x_m$ is minimal at each iteration if the search directions d_i are chosen to be A-orthogonal to the next error, i.e. $d_i^T A e_{i+1} = 0$. This makes the algorithm converge at the exact solution in n steps, but most importantly it allows to truncate the iterations without a large error on the approximation x_i.

In this case, the algorithm is called Conjugate Gradient Method and is formulated as

$$\alpha_i = \frac{r_i^T r_i}{d_i^T A d_i} \tag{3.17}$$

$$x_{i+1} = x_i + \alpha_i d_i \tag{3.18}$$

$$r_{i+1} = r_i - \alpha_i A d_i \tag{3.19}$$

$$\beta_{i+1} = \frac{r_{i+1}^T r_{i+1}}{r_i^T r_i} \tag{3.20}$$

$$d_{i+1} = r_{i+1} + \beta_{i+1} d_i \tag{3.21}$$

where iterations are truncated if the norm of the residual r_i is smaller than a certain threshold. CG represents a great method for sparse matrices, because it can be proven to be of complexity $O(m)$, where m is the number of non-zero elements in A [47].

Complex matrices   Algorithm (3.17) and the CG method in general can be used for complex matrices, under the condition that A is Hermitian and positive-definite when using the complex inner product, meaning that

$$A = A^\dagger \text{ and } x^\dagger A x > 0. \tag{3.22}$$

Preconditioning

The CG method convergence is known to be limited by the modulus of the condition number of A $\kappa(A)$, given by [47]

$$\kappa(A) = \frac{\lambda_{\max}(A)}{\lambda_{\min}(A)} \tag{3.23}$$

where $\lambda_{\max}$ and $\lambda_{\min}$ are respectively the largest and smallest eigenvalues of A in magnitude. If we were able to find a good *preconditioner* M, symmetric and positive-definite, such that $\kappa(M^{-1}A) \lll \kappa(A)$, and M^{-1} is easy to compute, then the algorithm would

converge much faster, by solving $M^{-1}Ax = M^{-1}b$, since x is also the solution of $Ax = b$.

$$x = (M^{-1}A)^{-1}M^{-1}b = A^{-1}MM^{-1}b = A^{-1}b. \tag{3.24}$$

Without delving into the details of the preconditioner implementation, detailed in [47], note that, in general, $M^{-1}A$ is neither positive-definite nor symmetric, which requires a Cholesky decomposition [31] $M = EE^T$ to be used, so that the problem may be restated with a symmetric positive-definite matrix $E^{-1}AE^{-T}$.

The catch with preconditioning is that M has no unique recipe. Preconditioners are widely spread across numerical analysis, so many methods have been explored and implemented [40].

Rayleigh-Ritz procedure

A common denominator of all these algorithms is the search of good approximations for the correct eigenvectors in a certain subspace. The method is called Rayleigh-Ritz (RR) procedure [45], and is here outlined.

Let us suppose to have a matrix A of size $n \times n$, with entries in $\mathbf{C}$ and a collection of vectors k organized in a matrix K, where K is of size $n \times k$. Generally speaking, n is large, while k is much smaller.

The best approximation of the true eigenvectors of A in the subspace $\mathcal{K}$ spanned by the vectors in K can be computed by solving the small scale eigenvalue problem

$$K^{\dagger}AKC = C\Lambda. \tag{3.25}$$

Here matrices $K^{\dagger}AK$ and C are of size $k \times k$. Computing KC gives a matrix of size $n \times k$, whose column vectors are the best approximations of the true eigenvectors of A in the subspace $\mathcal{K}$, with their corresponding eigenvalues in the entries of the diagonal matrix Λ.

Shift and Invert

The power iteration is the technique on which Krylov subspace search methods are based [21]. By repeatedly applying matrix A to a vector x, x gets skewed towards the eigenvector whose eigenvalue is of largest magnitude λ_n.

Assume A is a hermitian matrix, thus diagonalizable. This means we can write an arbitrary vector $x^{(0)}$ as a linear combination of the eigenvectors $\{v_i\}$ of A.

$$x^{(0)} = \sum_{i}^{n} \alpha_i v_i \tag{3.26}$$

If we apply A to $x^{(0)}$ k times, we get

$$x^{(k)} = A^k x^{(0)} = \sum_i^n \alpha_i A^k v_i = \sum_i^n \alpha_i \lambda_i^k v_i \tag{3.27}$$

It can be proven that the ratio of the j-th component of $x_j^{(k)}$ and $x_j^{(k-1)}$ converges to λ_n

$$\lim_{k \to \infty} \frac{x_j^{(k)}}{x_j^{(k-1)}} = \lambda_n \tag{3.28}$$

which means, that for large enough k, we have the relation

$$A x^{(k)} \approx \lambda_n x^{(k)} \tag{3.29}$$

So $x^{(k)}$ is an approximation of the eigenvector v_n of A whose eigenvalue is λ_n.

Smallest eigenvalue If instead of the largest eigenvalue, we were interested in the smallest one (in magnitude) λ_0, then we would need to apply the inverse matrix A^{-1} to $x^{(k)}$, which would change the ratio (3.28) to

$$\lim_{k \to \infty} \frac{x_j^{(k)}}{x_j^{(k-1)}} = \lambda_0 \tag{3.30}$$

Let us assume for a moment that we're solving a nuclear single-particle Hamiltonian, where we have a certain number of bound states of negative energy and a much larger number of unbound states with positive energy. In this case, the inverse power iteration would converge to the states whose energy is closer to zero, avoiding the interesting ones on the bottom of the spectrum.

The solution is, before inverting, to shift the matrix by a quantity σ that is very close to the lowest eigenvalue we want to compute, call it λ_σ (eigenvector v_σ). Now, the eigenvalue of lowest magnitude of $(A - \sigma I)$ is $\lambda_\sigma - \sigma$ and by applying $(A - \sigma I)^{-1}$ to $x^{(k)}$, we will get the approximation to the eigenvector v_σ.

3.2.2. Iterative eigensolvers

Now that the main techniques used by iterative eigensolvers have been laid out, we can look at three general methods, which are the most commonly used ones.

Jacobi-Davidson

The Jacobi-Davidson, where at each iteration by a correction to the previous eigenvectors. Given an approximation (u, θ) of an eigenpair of matrix A, where u is the approximate eigenvector and θ is the approximate eigenvalue, if the residual

$$r = Au - \theta u \tag{3.31}$$

is ≈ 0, then the eigenpair converged. Otherwise, we want to find a correction t such that

$$r = A(u + t) - (\theta + \delta\theta)(u + t) = 0 \tag{3.32}$$

Linearizing this equation in t gives

$$(A - \theta I)t = -r \tag{3.33}$$

To avoid singularity of the equation near convergence, since u approximately spans a subspace of the system's kernel $\ker(A - \theta I)$, and enrich the subspace search with a useful orthogonal correction, we project the problem onto the orthogonal subspace of u, which finally gives

$$(I - uu^\dagger)(A - \theta I)(I - uu^\dagger)t = -r \tag{3.34}$$

Algorithm 3.1 Jacobi-Davidson method

1: Choose normalized initial vectors $\{u_k\}$, set $V = [u_1, \ldots, u_k]$
2: **repeat**
3:     Compute Ritz pair: $T = V^\dagger A V$, solve $Ty = \theta y$
4:     Set $u = Vy$, residual $r = Au - \theta u$
5:     **if** $\|r_k\| < \varepsilon \ \forall k$ **then**
6:         **return** (θ, u)
7:     **end if**
8:     Solve approximately $(I - u_k u_k^\dagger)(A - \theta I)(I - u_k u_k^\dagger)t_k = -r_k$ using preconditioned iterative solver, ensuring $t_k \perp u_k$
9:     Normalize: $v_k = t_k / \|t_k\|$
10:     Expand subspace, setting $V = [V, v]$
11: **until** convergence for $k = 1, \ldots, \text{nev}$

Although simple, this method is computationally efficient only by using preconditioning,

which is known to be unstable in many cases [45].

Lanczos

Lanczos algorithm [32] is probably the most used iterative eigensolver in regards to hermitian matrices. It's a Krylov subspace search method, meaning the Rayleigh-Ritz procedure is done on a subspace formed as

$$\mathcal{K} = \{v_1, Av_1, A^2 v_1, \ldots, A^{k-1} v_1\} \tag{3.35}$$

which exploits the power iteration. After orthogonalizing the new approximation to the previous one and diagonalizing the small scale problem, we end up with the new best approximations to the eigenvectors of A.

Algorithm 3.2 Lanczos Method

1: Choose normalized initial vector v_1, set $\beta_0 = 0$, $m = $ subspace size.
2: **repeat**
3:     **for** $j = 1, 2, \ldots, m$ **do**
4:         $w \leftarrow Av_j - \beta_{j-1} v_{j-1}$
5:         $\alpha_j \leftarrow v_j^* w$
6:         $w \leftarrow w - \alpha_j v_j$
7:         $\beta_j \leftarrow \|w\|$
8:         **if** $\beta_j = 0$ **then**
9:             **break**
10:        **end if**
11:         $v_{j+1} \leftarrow w/\beta_j$
12:     **end for**
13:     Form tridiagonal matrix $T_m = \text{tridiag}(\beta_{1:m-1}, \alpha_{1:m}, \beta_{1:m-1})$
14:     Compute eigen-decomposition $T_m y_k = \theta_k y_k$, for $k = 1, \ldots, \text{nev}$
15:     Form Ritz approximations $x_k = V_m y_k$, where $V_m = [v_1, \ldots, v_m]$
16:     Compute residual norms $r_k = \|Ax_k - \theta_k x_k\|$ for all k
17: **until** convergence for $k = 1, \ldots, \text{nev}$

Lanczos is extremely efficient, memory- and CPU-wise for extremal eigenvalues, but this limits its applicability, as one may be interested in the inner portion of the eigenvalue spectrum, such in the case of Hartree-Fock-Bogoliubov (HFB).

A shift-and-invert strategy would be unfeasible in the case of large scale problems, since all Lanczos steps need to be performed exactly to avoid instabilities, a well known problem

in the Arnoldi generalization [45].

LOBPCG

The last algorithm of this short list is LOBPCG, it's the newest and most sophisticated one of the three.

Introduced by A. V. Knyazev in 1991 [28], it's a block, preconditioned conjugate gradient method, explicitly targeted at solving large-scale eigenvalue problems, and it has been used in modern solutions of the Schrödinger/KS equation in recent years [33, 35, 39, 55]. We won't go into the details of LOBPCG, since GCG shares with it many aspects, like blocking and search directions calculation.

LOBPCG works very well for large scale problems, but it has limitations. For one, it's not possible to arbitrarily select the portion of the matrix spectrum to calculate, which is required for problems where variational collapse happens, like in HFB or the Dirac equation, which manifests particle/antiparticle solutions [33]. To solve this, an additional filtering step is required [33, 35], which introduces a computational cost in the algorithm. Lastly, LOBPCG may fail when poor conditioning is present or when high precision on the eigenvalues is required [34].

3.2.3. General Conjugate Gradient

The General Conjugate Gradient is an iterative eigensolver designed with the aim of improving LOBPCG, it is a blocked algorithm, which uses the inverse power method and previous search directions to generate the search subspace. GCG is proven to be faster and more stable than LOBPCG [34].

The search subspace is built as

$$V = [X, P, W], \tag{3.36}$$

where X is the matrix containing the approximations to the eigenvectors of matrix A, P is the matrix containing the previous search directions, and W is the matrix containing the eigenvectors on which the inverse power method is applied approximately using CG. A slightly different implementation of the algorithm is employed in the present work, detailed in algorithm 3.3, to improve applicability to HF calculations and reduce the computational cost.

Eigenvalue problem   The original algorithm aims at solving the general eigenvalue problem $AX = \lambda BX$. Since in our case $B = I$, it is omitted from the procedure, reducing the computational cost of the algorithm, in particular, the one of the search direction

block P. After orthonormalization of V, the columns of X are orthonormal as well and the calculation of P is given by

$$P = X_{\text{new}} - X(X^\dagger X_{\text{new}}) \qquad (3.37)$$

which is the projection of X_{new} onto the orthogonal complement of X.

Complex matrix The algorithm has been generalized to the complex case, where the matrix is complex Hermitian, as such, the transposition operation is replaced by the conjugate transpose.

Blocking The algorithm is designed to allow blocking of the eigenvectors, such that $X = [X_c, X_a, X_r]$, where X_c are the converged eigenvectors, X_a are the active eigenvectors on which we perform the inverse power iteration, with $\text{col}(X_a)$ being a fixed number, and X_r are the remaining eigenvectors, which are to be inserted in X_a as soon as some of its columns converge. This allows to save some computations by avoiding the expensive inverse power on pairs that have already converged. Since in a self-consistent calculation the matrix changes rapidly and at each HF iteration, it is the case that the maximum number of iterations is reached before convergence of all eigenpairs, so we must work at all times on the remaining unconverged eigenvectors. For this reason, we only implement the $X = [X_c, X_a]$ scheme.

Orthogonalization The original paper [34] suggests an improved orthogonalization procedure; being beyond the scope of this work, the simpler Gram-Schmidt [6] orthogonalization is used in the present work.

Shift update The shift update is either fixed, in case of known spectrum, eg for HFB `shift = 0`, or adaptive [34], so that the inverse power step can find the lowest eigenvalues, using the update formula

$$\texttt{shift} = (\lambda_{\text{nev}} - 100\lambda_1)/99 \qquad (3.38)$$

where λ_{nev} is the biggest eigenvalue of the RR procedure and λ_1 is the smallest of the active eigenpairs.

Preconditioning The use of a preconditioner is beyond the scope of this work, a simple diagonal preconditioner is used.

Algorithm 3.3 General Conjugate Gradient algorithm

1: **Input:** Matrix A, number of desired eigenpairs `nev`, X_{guess} initial guess with $\text{col}(X_{\text{guess}}) = k \geq$ `nev`, `max_iter` maximum number of iterations.

2: Initialize block $X = [X_{\text{c}}, X_{\text{a}}] \leftarrow X_{\text{guess}}$

3: Initialize blocks P and W with k null vectors

4: Solve the Rayleigh Ritz problem $X^{\dagger}AXC = C\Lambda$

5: Update $X = XC$

6: Initialize `shift`, Initialize `iter` $= 0$

7: **while** $\text{col}(X_c) <$ `nev` and `iter` $<$ `max_iter` **do**

8:     Solve approximately $(A + \text{shift} \cdot I)W = X_a\Lambda$ with some CG steps, initial value X_a to generate W

9:     Orthogonalize $V = [X, P, W]$

10:     Solve the Rayleigh Ritz problem $V^{\dagger}(A + \text{shift} \cdot I)VC = C\Lambda$

11:     Update $X_{\text{new}} = (VC)(:, \text{nev})$ and $\Lambda_{\text{new}} = \Lambda - \text{shift} \cdot I$

12:     Compute $P = X_{\text{new}} - X(X^{\dagger}X_{\text{new}})$

13:     Compute the residual $R = AX_{\text{new}} - \Lambda X_{\text{new}}$

14:     Check convergence on k-th column norm of R, if $\|R(:,k)\| <$ `tol`, move $X_a(:,k)$ to X_c.

15:     Update `shift` and `iter`

16: **end while**

17: **Output:** Approximate eigenpairs (Λ, X)

3.3.   Code implementation details

In this last section regarding numerical methods, some important features about the actual code implementation of the HF method are discussed. Mainly, the implementation of the Augmented Lagrangian Method to enforce spatial constraints on the HF solution, the pseudocode of the entire self-consistent procedure, and the choice of optimal parameters for the functional minimization.

3.3.1.   Constraints

The purpose of spatial constraints is to find the minimum of the energy functional under the condition that the expectation value of a given operator $\mathcal{Q}$ equals a prescribed target value q_0. Constrained calculations are a fundamental tool to assess the stability of the ground-state minimum and to investigate dynamical properties of the nucleus, such as fission barriers [7].

Constraints can be formulated as an equality-constrained optimization problem (ECP), formulated as

$$\min_{|\Psi\rangle} E \qquad (3.39)$$

$$\text{constrainted to } \langle\Psi|\, \mathcal{Q}\, |\Psi\rangle = \langle\mathcal{Q}\rangle = q_0 \qquad (3.40)$$

Which yields the Lagrangian

$$E' = E + \lambda(\langle\mathcal{Q}\rangle - q_0) \qquad (3.41)$$

where λ is a Lagrange multiplier determined by the condition $\langle\mathcal{Q}\rangle = q_0$. After finding the minimum of E', it's trivial to show that for a given λ, we get [19]

$$\frac{\mathrm{d}E}{\mathrm{d}\langle\mathcal{Q}\rangle} = -\lambda. \qquad (3.42)$$

From a numerical standpoint, λ needs to be tuned at each iteration to reach the desired value of q_0. This method was the one used in early constrained Hartree-Fock calculations [15].

Although this method is simple, it often fails. Moreover, for the same value of λ, many, possibly infinite values of $\langle\mathcal{Q}\rangle$ can be obtained, for which we are only allowed to get the one with the most stable solution.

A different method is provided by the Quadratic Penalty Method (QPM). Briefly speaking, instead of a Lagrange multiplier, we add a quadratic contribution to the functional, such that

$$E' = E + \frac{c}{2}(\langle\mathcal{Q}\rangle - q_0)^2. \qquad (3.43)$$

This is a straightforward method; intuitively one penalizes (hence the name), any solution for which $\langle\mathcal{Q}\rangle \neq q_0$ by increasing its energy. However, the success of such procedure is heavily influenced by the choice of c, often leading to instabilities for large values.

What happens is that for small values of c, the penalty may be insufficient to reach the target q_0, while for bigger values, the penalty may be so strong that the self-consistent calculation oscillates and fails.

Augmented Lagrangian Method

A modern, robust approach, used by HF/HFB codes [11, 44] is given in the form of the Augmented Lagrangian Method (ALM) [49]. Its main idea is to combine the precision of the ECP with the accuracy of the QPM.

Without delving into cumbersome mathematical details, we'll see how the algorithm is practically implemented in the code.

Given the functional

$$E' = E + \lambda(q - q_0) + \frac{c}{2}(q - q_0)^2 \tag{3.44}$$

where $q = \langle \mathcal{Q} \rangle$, the resulting mean field potential will be given by

$$U' = U + \lambda\mathcal{Q} + c(q - q_0)\mathcal{Q} \tag{3.45}$$

$$= U + c(q - q_0(\lambda))\mathcal{Q} \tag{3.46}$$

where $q_0(\lambda)$ is updated at each iteration with the formula

$$q_0(\lambda) = q_0 - \frac{\lambda}{c} \tag{3.47}$$

$$\lambda^{(i+1)} = \lambda^{(i)} + \mu c(q - q_0) \tag{3.48}$$

Here, a slight deviation from the original ALM is present. Since the original work [49] doesn't provide guidance regarding what is considered an *iteration*, we employ the strategy [11] of using a damping factor $\mu \in [0, 1]$, so λ can be updated at each HF iteration for fast convergence, without large oscillations or instabilities of any kind.

This method is what powers the deformation curves that are shown in chapter 5, allowing to explore the energy surface with arbitrary precision in reaching the value of q_0 at convergence, provided that enough HF iterations are performed.

Note that, since $\lambda^{(0)} = 0$, for $\mu = 0$ ALM reduces to the standard QPM.

3.3.2. Details on the implementation of the code

The whole Hartree-Fock framework presented up to this point, has been implemented using the C++ language [51] and the Eigen linear algebra library [23], which implements linear algebra operatrions through low level routines such as `LAPACK` and `BLAS`. In figure 3.1, the schematics of the program structure is reported.

3.3.3. Optimal parameters choice

Inside the 'Diagonalize h' step in figure 3.1, the execution of the GCG algorithm is performed, using the current iteration's single-particle Hamiltonian as the matrix to diagonalize and the previous iteration's orbitals as the initial guess. This is the main computational bottleneck of the code, where a correct choice of the execution parameters can drastically reduce execution times. The paramters that need to be chosen carefully are essentially the inverse power step tolerance and the number of maximum GCG iterations.

Code
- Parse user input
- Generate mesh
- Solve (deformed) Woods-Saxon
  - Generate harmonic oscillator guess
  - Diagonalize Woods-Saxon hamiltonian
- Normalize wavefunctions
- HF iterations
  - Solve BCS self-consistent equations
  - Generate iteration data
    - Generate new densities, mix with previous ones
    - Generate mean fields
    - Generate constraint fields, mix with previous ones
  - Compute single-particle hamiltonian
  - Diagonalize h
  - Normalize wavefunctions
  - Check convergence
    - Compute energies, constraints residuals
    - If above tolerance
- Generate output
  - Compute multipole moments, energies, quantum numbers
 - Write program output

Figure 3.1: Pseudocode of the Hartree-Fock program.

Inverse power step tolerance

The first parameter to be tuned is the tolerance on the CG step which approximately solves the system

$$(A + \texttt{shift} \cdot I)W = X_a \Lambda \tag{3.49}$$

in algorithm 3.3, where A is actually the single-particle Hamiltonian h. When the CG residual $(A + \texttt{shift} \cdot I)W - X_a\Lambda$ is smaller than the tolerance, the procedure stops and outputs the W block.

In figure 3.2, the relative absolute error of the total energy is calculated against a reference benchmark value (details in the results chapter 4), for different values of the CG tolerance. It's clear that at least a tolerance of 10^{-3} is needed for good convergence, while tolerances $\geq 10^{-4}$ stop offering increasing returns, rendering a choice between 10^{-4} and 10^{-5} an optimal one.
Figure 3.2: HF calculation convergence with varying CG tolerance for ^{16}O, box $[-9, 9]$ fm, step size 0.3 fm.

Inner GCG iterations

The number of inner GCG maximum iterations, here named 'inverse power steps' to avoid confusion, is slightly more nuanced than the CG tolerance. The algorithm converges to the true eigenpairs as the power steps are performed, so one could think that a higher number of steps would bring to HF convergence faster, since the precision on the eigenvalues increases, but this is not the case.

In figures 3.3 and 3.4, the convergence of the HF calculation is plotted for different number

of steps, respectively, for the spherical nucleus ^{16}O and the deformed nucleus ^{24}Mg.

**Figure 3.3:** HF calculation convergence with varying number of inverse power steps for ^{16}O, box $[-9, 9]$ fm, step size 0.3 fm.

Figure 3.4: HF calculation convergence with varying number of inverse power steps for the deformed nucleus ^{24}Mg, box $[-10, 10]$ fm, step size 0.33 fm.

It's evident that in both cases, a steps number greater than 3 leads to oscillating behaviour

near convergence, without accelerating it, while in the case of the spherical nucleus, just one step is enough to quickly, and reliably reach convergence. In any case, it's clear that delaying the inverse power steps to later HF iterations is safer in terms of stability.

This counter intuitive behavior is likely due to the fact that at each HF iteration the hamiltonian changes and a great number of steps leads to solutions too biased towards the current matrix eigenpairs, at the expense of the next iteration; however, in the case of deformed nuclei, due to sharp shape changes at the start of the calculation, just one step may not be enough to sustain the pace at which the Hamiltonian changes, hence the quicker convergence with more steps.

3.3.4. Numerical stability

As a final remark, the numerical stability of the solver is reported in figure 3.5. The map is produced for a spherical calculation of ^{16}O, with varying box and mesh sizes.

It's possible to observe that for a box whose side is at least ≈ 2.5 times the nuclear radius, the solver numerical stability is loosely dependent on the box extension, but rather on the step size. This is not surprising, as the points separation in space h dictates the precision of the discretized derivatives, as mentioned in section 3.1.
Figure 3.5: Numerical stability map of the HF solver for ^{16}O for different box and step sizes. Relative error is taken against a benchmark reference value.

4 | Results for spherical nuclei

In this chapter, results for spherical nuclei are presented. These are mostly calculated for double magic nuclei, with the exception of ^{90}Zr. The reason behind choosing spherical nuclei as an initial benchmark, is that numerous spherical HF codes are available and they have the advantage of being one-dimensional, which allows the use of very fine meshes, with a step size that can go down to the physical scale of the problem, which is roughly 0.1 fm in this case, without any major computational limit. We can use these codes as a reference ideal value for the different quantities produced by our code. The choice for benchmarking spherical results in the present work has been the `hfbcs_qrpa` code [13]. This chapter is structured as follows. In section **??**, some physical properties of the system are presented, such as the mean square radii and the deformation parameters, which we can use to numerically validate the code. In section **??**, benchmark results for ^{16}O are presented, while in section **??** results for the heavier nuclei ^{48}Ca, ^{56}Ni, and ^{90}Zr are shown.

4.1. Physical quantities

After finding a nuclide's ground state, we are able to compute different physical properties of the system. We can use these values as a numerical reference when comparing our results with other codes.

4.1.1. Mean square radii

An important set of quantities characterizing the nuclear density is certainly the one of mean square radii. The individual nuclear spieces' mean square radius is defined as

$$\left\langle r_q^2 \right\rangle = \frac{\int \rho_q(\boldsymbol{r}) r^2 d\boldsymbol{r}}{\int \rho_q(\boldsymbol{r}) d\boldsymbol{r}}. \tag{4.1}$$

While the charge mean square radius formula is derived from the convolution of the neutron and proton particle densities with their respective internal charge distribution

[4], resulting in equation (4.2).

$$\langle r_{ch}^2 \rangle = \langle r_p^2 \rangle + \langle r^2 \rangle_P + \frac{N}{Z} \langle r^2 \rangle_N + \frac{2}{Z} \left(\frac{\hbar}{mc} \right)^2 \sum_{\alpha q} \mu_q \langle \boldsymbol{\sigma} \cdot \boldsymbol{\ell} \rangle_{\alpha q} \tag{4.2}$$

where q runs over the nuclear species and α runs over all single particle states of spcies q. $\boldsymbol{\sigma}$ is the vector operator of Pauli matrices, while $\boldsymbol{\ell}$ is the angular momentum operator $-i(\boldsymbol{r} \times \nabla)$. $\langle r^2 \rangle_P$ and $\langle r^2 \rangle_N$ refer to the square charge radii of the proton and the neutron, while μ_q to their respective magnetic dipole moment in units of nuclear magneton.

All square charge radii computed in this work use the set of parameters in table 4.1, taken to be equal to the spherical benchmark code `hfbcs_qrpa`.

Parameter	Value	Units
$\langle r^2 \rangle_P$	0.64	fm^2
$\langle r^2 \rangle_N$	-0.11	fm^2
μ_p	2.792847	-
μ_n	-1.913043	-

Table 4.1: Parameters used to compute the charge mean square radius.

4.1.2.   Deformation parameters

When dealing with deformed nuclei, mean square radii are not sufficient to characterize the nuclear density. The main parameter used is the quadrupole deformation parameter β_2, similar to the one encountered in section 1.3, it can be computed through the actual mean square radius with formula (4.3)

$$\beta_2 = \frac{4\pi \langle Y_{20} \rangle}{3A \langle r^2 \rangle} \tag{4.3}$$

where $\langle r^2 \rangle$ is the total mean square radius of the nucleus

$$\langle r^2 \rangle = \frac{\int (\rho_n + \rho_p) r^2 d\boldsymbol{r}}{\int (\rho_n + \rho_p) d\boldsymbol{r}} = \langle x^2 + y^2 + z^2 \rangle . \tag{4.4}$$

For spherical nuclei, $\beta_2 = 0$, while for deformed ones, thanks to the normalization with respect to the total radius and mass, the β_2 parameter can be used to compare different nuclei across the nuclide chart.

4.2.   Parameters and mesh choice

All `hfbcs_qrpa` calculations were performed using a mesh size of 0.1 fm, no pairing interaction, and a radial mesh size whose radius is equal to the side of the box in our computation. The lattice of our code depends on the extension of the nucleus, which is directly determined by its mass A; since the number of subdivisions that allows reasonable CPU times on a laptop caps around $60 - 70$, step sizes vary across different calculations. In the results shown here, for ^{16}O, we are able to reach a 0.3 fm step size, while for the heaviest, ^{90}Zr, we are only able to reach 0.42 fm. The reason behind this choice is that as the nucleus size increases, a bigger box is needed to ensure that all relevant states are able to decay to zero at the boundary. All the data reported in this chapter is computed with the SLy5 parametrization [10].

4.3.   Results for ^{16}O

The first results we will take a look at are the ones for ^{16}O. It's the best candidate for gauging the solver's performance, as it is a very light, double magic nucleus, meaning it has no pairing interaction and a spherical shape.

All calculations are performed on a box of size $[-9, 9]$ fm in all three directions and a step size of 0.3 fm, correponding to $2 \cdot 60^3$ mesh points.

4.3.1.   Results neglecting Coulomb interaction

Since the Skyrme functional is complex and nuanced, results are shown for more and more terms in expression (2.100). We start by including only C_0^ρ, C_1^ρ, C_0^τ, C_1^τ and neglecting the others and the Coulomb interaction; results are reported in table 4.2. Without further terms, the spin-orbit field $\boldsymbol{B}(\boldsymbol{r})$ vanishes, hence the $1p_{3/2}$ and $1p_{1/2}$ levels show degeneration in energy.

Since $N = Z$, assuming equal masses the single-particle equations will be exactly equal between the two species, therefore only neutron results are reported. Note that C_1 terms reduce to being null in this case, that is until we either break the $N = Z$ equality or introduce the Coulomb interaction. In table 4.3 the $C_0^{\boldsymbol{\nabla} \cdot \boldsymbol{J}}$ and $C_1^{\boldsymbol{\nabla} \cdot \boldsymbol{J}}$ terms are included just for the spin-orbit field $\boldsymbol{B}(\boldsymbol{r})$, but not for the mean field $U(\boldsymbol{r})$; from an interaction point of view, it's as if we were neglecting the spin-gradient coupling term [10]. As expected, the $1p_{3/2}$ and $1p_{1/2}$ degeneration is removed, displaying the spin-orbit splitting, which lowers the total angular momentum $j = 3/2$ level and raises the $j = 1/2$ level.

Lastly, the $C_0^{\boldsymbol{\nabla} \cdot \boldsymbol{J}}$ and $C_1^{\boldsymbol{\nabla} \cdot \boldsymbol{J}}$ terms are also included in the calculation of the mean-field,

resulting in the full implementation of the Skyrme functional. As shown in table 4.4, the effect of this addition on the ground state is little, as the spin current $J_{\mu\nu}$ is small in light, closed shell nuclei.

Results including Coulomb interaction

As the final addition to get a complete and accurate description of ^{16}O, the Coulomb interaction is included as detailed in section 2.4. Results are shown in table 4.5.
As shown in tables 4.2, 4.3, 4.4, and 4.5 results for ^{16}O are in great agreement with the output of the `hfbcs_qrpa` code for all the terms in the Skyrme functional.

4.4.   Results for heavier nuclei

In the following section, results for some spherical nuclei heavier than ^{16}O are presented in tables 4.6, 4.7 and 4.8. Our code still shows good agreement with the `hfbcs_qrpa` one. A slight increase of the numerical error can be observed as the step size increaseas, which is compatible with the polynomial error in the finite difference method.

4.4.1.   Comparison with experimental binding energies

The Skyrme functional is highly successful at producing theoretical values in great accordance with experimental data, just by fitting a small set of parameters [2]. In table 4.9, binding energies of some of the nuclei studied in this work are compared with experimental values, taken from the Atomic Mass Data Center [1].

5 | Results for deformed nuclei

Having established that the code works well for spherical nuclei, we can start treading in deformation territory.

5.1. ^{24}Mg

In the following section, results for ^{24}Mg are presented, it's a natural choice to study how well deformations are represented by our framework, since it's light, very deformed and shows no pairing interaction in its ground state.

5.1.1. `HFBTHO` code and calculation details

`HFBTHO`

To benchmark the code in the case of nuclear deformation, the `HFBTHO` code was used [36], it's a HFB code which minimizes the energy functional on a (Transformed) harmonic oscillator basis. Since ^{24}Mg is a light nucleus, it still works well in this case. All calculations were performed using 12 oscillator shells and assuming a zero pairing interaction. Default parameters were adopted for the quadrupole constraints. Since the version of `HFBTHO` used in this work has been compiled with the J^2 terms disabled, we present the results from our code both with and without them. The results obtained without them serve as a benchmark for the code, while those including the J^2 contribution illustrate their impact on the calculated observables.

Code parameters and axial constraint

As for our code, calculations are performed on a box $[-10, 10]$ fm. In the case of the ground state calculation, a step size of 0.33 fm is used, with a starting guess of a deformed Woods-Saxon with $\beta_2 = 0.4$.

The calculation in the case of the deformation curve is carried out imposing the following

constraints

$$\langle \text{Re}\, Q_{22} \rangle = 0 \tag{5.1}$$

$$\langle \text{Im}\, Q_{22} \rangle = 0 \tag{5.2}$$

$$\langle Y_{20} \rangle = q_{20}. \tag{5.3}$$

These constraints altogether impose an axial deformation on the system. This is done because on a full mesh like in our case, the nucleus may deform on a different axis from the chosen one (z), resulting in spurious contributions to the real deformation curve; moreover, the axial symmetry of HFBTHO doesn't allow broken axial symmetry configurations. Regarding the stiffness c and damping parameter μ of ALM in section 3.3.1, $c = 0.001$ and $\mu = 0.1$ were used. As for convergence criteria, a tolerance of 0.001 on the value of $\beta_2 - \beta_{2,\text{target}}$ was used.

Ground state

Table 5.1 reports data of the comparison for the ground state of ^{24}Mg, while figure 5.1 shows the middle section of the total particle density. Charge radii for the two codes are displayed but not compared, due to different formulas used for their computation. $\langle x^2 \rangle, \langle y^2 \rangle$ and $\langle z^2 \rangle$ is reported for our code but not for HFBTHO since it doesn't compute them.

		GCG	GCG no J^2	HFBTHO	Δ	$\Delta\%$

Table 5.1: Results for ^{24}Mg ground state, no pairing interaction, box $[-10, 10]$ fm, step size 0.33 fm, SKM* parametrization.

The comparison shows good agreement between the two codes, with the same β_2 minimum and similar ground state properties.
Figure 5.1: Magnesium ground state density $\rho(x, y, 0)$, calculation done on a box $[-10, 10]$ fm, step size 0.33 fm, SKM* parametrization

Deformation curve

In figure 5.2, the deformation curve is shown for ^{24}Mg, without pairing. To counteract the sharp rise in CPU time, due to the high number of points in the curve, a coarser lattice than the one in the ground state calculation is used, hence the shift in energy of the curve.

Figure 5.2 shows the same trend for both codes, with a minimum of the energy in $\beta_2 = 0.390$, albeit a difference in the energies due to the corase mesh, a gap which is shown in table 5.1 to shrink when increasing the accuracy of the step size.
Figure 5.2: Magnesium deformation curve, no pairing interaction, calculation done on a box $[-10, 10]$ fm, step size 0.66 fm, SKM* parametrization, neglecting J^2 terms.

A | Appendix

A.1. Spherical harmonics

Spherical harmonics, of order λ, μ, are defined as

$$Y_{\lambda\mu}(\theta, \phi) = (-1)^{\mu}\sqrt{\frac{2\lambda+1}{4\pi}\frac{(\lambda-\mu)!}{(\lambda+\mu)!}}\, P_{\lambda}^{\mu}(\cos\theta)\, e^{i\mu\phi}. \tag{A.1}$$

Being able to provide the expression for arbitrary μ, λ through an algorithm is important in the current framework, to solve the Poisson equation and investigate nuclear properties. The major challenge is to generate the associated Legendre polynomials P_{λ}^{μ}. They can be expressed in the form (for positive μ)

$$P_{\lambda}^{\mu}(x) = (1-x^2)^{\mu/2}\frac{\mathrm{d}^{\mu}P_{\lambda}(x)}{\mathrm{d}x^{\mu}}, \tag{A.2}$$

where $x = \cos\theta$ and

$$P_{\lambda}(x) = \frac{1}{2^{\lambda}\lambda!}\frac{\mathrm{d}^{\lambda}(x^2-1)^{\lambda}}{\mathrm{d}x^{\lambda}}. \tag{A.3}$$

To compute the arbitrary λ, μ associated Legendre polynomial we can employ a recursive approach, setting $\lambda = \mu$

$$P_{\mu}^{\mu}(x) = (2\mu-1)!!\,(1-x^2)^{\mu/2}, \tag{A.4}$$

where $(2\mu-1)!! = 1\cdot 3\cdot 5\ldots(2\mu-1)$ denotes the double factorial. Once $P_{\mu}^{\mu}(x)$ is known, the next element with $\lambda = \mu+1$ reads

$$P_{\mu+1}^{\mu}(x) = x(2\mu+1)P_{\mu}^{\mu}(x). \tag{A.5}$$

All higher orders are then generated using the standard upward recurrence relation in λ:

$$(\lambda-\mu+1)\,P_{\lambda+1}^{\mu}(x) = (2\lambda+1)\,x\,P_{\lambda}^{\mu}(x) - (\lambda+\mu)\,P_{\lambda-1}^{\mu}(x), \tag{A.6}$$

valid for all $\lambda \geq \mu+1$.

A.1.1. Algorithm

1. Compute the base case P_μ^μ from the closed-form formula.

2. If $\mu = \lambda$ the procedure ends, otherwise

3. Evaluate $P_{\mu+1}^\mu$, if $\lambda = \mu + 1$ the procedure ends, otherwise

4. Apply the recurrence relation $P_{\lambda+1}^\mu$ until the desired degree is reached

This ought to be applied only for $\mu \geq 0$. For $\mu < 0$ the procedure is carried out using $-\mu$ and in the end using the relation

$$Y_{\lambda-\mu} = (-1)^\mu Y_{\lambda\mu}^* \tag{A.7}$$

A.2. 5-point derivatives

The first and second derivatives of a function $\psi(x)$ in $x = x_i$, using 5-points formulae, read

$$\psi'(x_i) = \frac{\psi_{i-2} - 8\psi_{i-1} + 8\psi_{i+1} - \psi_{i+2}}{12h} \tag{A.8}$$

$$\psi''(x_i) = \frac{-\psi_{i-2} + 16\psi_{i-1} - 30\psi_i + 16\psi_{i+1} - \psi_{i+2}}{12h^2} \tag{A.9}$$

A.3. Functional derivatives

Given a functional $\mathcal{F}[\rho]$, the functional derivative is defined as the variation of $\mathcal{F}$ with respect to a small change in the density ρ, formally

$$\frac{\delta\mathcal{F}[\rho]}{\delta\rho} = \lim_{\delta\rho \to 0} \frac{\mathcal{F}[\rho + \delta\rho] - \mathcal{F}[\rho]}{\delta\rho}.$$

Power dependence Let us suppose to have $\mathcal{F}[\rho] = A\rho^\sigma$, where A is a constant. A variation $\delta\rho$ of ρ yields

$$\mathcal{F}[\rho + \delta\rho] - \mathcal{F}[\rho] = A\big[(\rho + \delta\rho)^\sigma - \rho^\sigma\big].$$

Expanding to first order in $\delta\rho$ (Taylor expansion) we obtain

$$(\rho + \delta\rho)^\sigma = \rho^\sigma + \sigma\rho^{\sigma-1}\,\delta\rho + \mathcal{O}((\delta\rho)^2),$$

hence

$$\mathcal{F}[\rho + \delta\rho] - \mathcal{F}[\rho] = A\,\sigma\,\rho^{\sigma-1}\,\delta\rho + \mathcal{O}((\delta\rho)^2).$$

Dividing by $\delta\rho$ and taking the limit $\delta\rho \to 0$ gives the usual result for the functional derivative

$$\frac{\delta\mathcal{F}[\rho]}{\delta\rho} = A\,\sigma\,\rho^{\sigma-1}. \tag{A.10}$$

Divergence of a vector field Consider the functional

$$\mathcal{G}[\boldsymbol{J}](\boldsymbol{r}) = \nabla_r \cdot \boldsymbol{J}(\boldsymbol{r}).$$

A small variation $\delta\boldsymbol{J}$ induces

$$\delta\mathcal{G}(\boldsymbol{r}) = \nabla_r \cdot \delta\boldsymbol{J}(\boldsymbol{r}).$$

We can express the variation $\delta\boldsymbol{J}(\boldsymbol{r})$ in terms of its values at all points $\boldsymbol{r}'$ as

$$\delta\boldsymbol{J}(\boldsymbol{r}) = \int d^3r'\,\delta\boldsymbol{J}(\boldsymbol{r}')\,\delta(\boldsymbol{r} - \boldsymbol{r}').$$

Substituting this into the expression for $\delta\mathcal{G}(\boldsymbol{r})$ yields

$$\delta\mathcal{G}(\boldsymbol{r}) = \int d^3r'\,\nabla_r \cdot \left[\delta\boldsymbol{J}(\boldsymbol{r}')\,\delta(\boldsymbol{r} - \boldsymbol{r}')\right].$$

Since $\boldsymbol{r}$ and $\boldsymbol{r}'$ are independent variables, the derivative acts only on the delta function:

$$\delta\mathcal{G}(\boldsymbol{r}) = \int d^3r'\,\left(\nabla_r\delta(\boldsymbol{r} - \boldsymbol{r}')\right)\cdot\delta\boldsymbol{J}(\boldsymbol{r}').$$

By the definition of the functional derivative as the kernel relating $\delta\mathcal{G}(\boldsymbol{r})$ to $\delta\boldsymbol{J}(\boldsymbol{r}')$, we can read off

$$\frac{\delta\,\mathcal{G}[\boldsymbol{J}](\boldsymbol{r})}{\delta\boldsymbol{J}(\boldsymbol{r}')} = \nabla_r\,\delta(\boldsymbol{r} - \boldsymbol{r}'). \tag{A.11}$$

In compact vector form [27],

$$\frac{\delta\left(\nabla_r\cdot\boldsymbol{J}(\boldsymbol{r})\right)}{\delta\boldsymbol{J}(\boldsymbol{r}')} = \nabla_r\,\delta(\boldsymbol{r} - \boldsymbol{r}').$$

A.4. $\overline{U},\ \overline{V}$ **matrix structure**

The blocked form of the $\overline{U}$ and $\overline{V}$ matrices in section **??** is given by

$$
\bar{U} = \begin{pmatrix}
0 & & & & & & \\
& u_1 & 0 & & & & \\
& 0 & u_1 & & & & \\
& & & \ddots & & & \\
& & & & u_n & 0 & \\
& & & & 0 & u_n & \\
& & & & & & 1
\end{pmatrix}
$$

$$
\bar{V} = \begin{pmatrix}
1 & & & & & & \\
& 0 & v_1 & & & & \\
& -v_1 & 0 & & & & \\
& & & \ddots & & & \\
& & & & 0 & v_n & \\
& & & & -v_n & 0 & \\
& & & & & & 0
\end{pmatrix}
$$
